AMERICAN PUBLIC HEALTH ASSOCIATION
GOVERNING COUNCIL

OFFICERS 1948–1949

President, Charles F. Wilinsky, M.D., Boston, Mass.
President-Elect, Lowell J. Reed, Ph.D., Baltimore, Md.
Vice-President, Guillermo Arbona, M.D., Santurce, P. R.
Vice-President, Albert E. Berry, Ph.D., Toronto, Ont.
Vice-President, Florence R. Sabin, M.D., Denver, Colo.
Treasurer, Louis I. Dublin, Ph.D., New York, N. Y.
Chairman of Executive Board, Hugh R. Leavell, M.D., Boston, Mass.
Executive Secretary, Reginald M. Atwater, M.D., New York, N. Y.

EXECUTIVE BOARD

Chairman, Hugh R. Leavell, M.D., Boston, Mass. (1949)
Leona Baumgartner, M.D., New York, N. Y. (1951)
Louis I. Dublin, Ph.D., New York, N. Y. (Treasurer)
Edward G. McGavran, M.D., Chapel Hill, N. C. (1949)
Lowell J. Reed, Ph.D., Baltimore, Md. (President-Elect)
Thomas F. Sellers, M.D., Atlanta, Ga. (1951)
George M. Uhl, M.D., Los Angeles, Calif. (1950)
Estella F. Warner, M.D., Washington, D. C. (1950)
Charles F. Wilinsky, M.D., Boston, Mass. (President)

ELECTIVE COUNCILORS

Terms Expiring 1949

Gaylord W. Anderson, M.D., Minneapolis, Minn.
A. J. Chesley, M.D., Minneapolis, Minn.
Harold S. Diehl, M.D., Minneapolis, Minn.
Ira V. Hiscock, Sc.D., New Haven, Conn.
Pearl L. Kendrick, Sc.D., Grand Rapids, Mich.
James P. Leake, M.D., Washington, D. C.
Hugh R. Leavell, M.D., Boston, Mass.
George T. Palmer, Dr.P.H., San Francisco, Calif.
James G. Townsend, M.D., Bethesda, Md.
Felix J. Underwood, M.D., Jackson, Miss.

Terms Expiring 1950

George Baehr, M.D., New York, N. Y.
Earnest Boyce, C.E., Ann Arbor, Mich.
Ruth E. Boynton, M.D., Minneapolis, Minn.
Mayhew Derryberry, Ph.D., Washington, D. C.
Thomas Francis, Jr., M.D., Ann Arbor, Mich.
Wilton L. Halverson, M.D., San Francisco, Calif.
Roy J. Morton, M.S., Oak Ridge, Tenn.
Joseph W. Mountin, M.D., Washington, D. C.
Bosse B. Randle, R.N., Mineola, N. Y.
Huntington Williams, M.D., Baltimore, Md.

Terms Expiring 1951

Charles F. Blankenship, M.D., Carson City, Nev.
Roy F. Feemster, M.D., Boston, Mass.
John E. Gordon, M.D., Boston, Mass.
Herman E. Hilleboe, M.D., Albany, N. Y.
Benjamin G. Horning, M.D., Battle Creek, Mich.
James E. Perkins, M.D., New York, N. Y.
Ruth R. Puffer, Dr.P.H., Nashville, Tenn.
James S. Simmons, M.D., Boston, Mass.
Dean F. Smiley, M.D., Chicago, Ill.
Myron E. Wegman, M.D., New Orleans, La.

SECTION OFFICERS

Health Officers

Chm., Stanford F. Farnsworth, M.D., Oakland, Calif.
Vice-Chm., John M. Whitney, M.D., Washington, D. C.
Secy., Joseph G. Molner, M.D., Detroit, Mich.

CONSTITUTION AND BY-LAWS

AMERICAN PUBLIC HEALTH ASSOCIATION

As Adopted at the Seventy-sixth Annual Meeting, November 10, 1948

CONSTITUTION

ARTICLE I NAME

The name of this Association, incorporated under the laws of Massachusetts, is the American Public Health Association.

ARTICLE II OBJECT

The object of this Association is to protect and promote public and personal health.

ARTICLE III MEMBERSHIP

Section 1. There shall be seven classes of constituents to be designated as Fellows, Honorary Fellows, Members, Sustaining Members, Life Members, Affiliated Societies, and Regional Branches.

Section 2. The right to hold office, except the office of Vice-President, or to serve as a member of the Governing Council, the Executive Board, or of a Section Council, or of a standing committee, or as the chairman of a committee of the Association or of a Section, or to vote for elective Councilors or on any amendment to the Constitution shall be limited to Fellows and to Life Members and Honorary Fellows who have been elected Fellows of the Association.

Section 3. The qualifications of the several classes of constituents, and the dues of each of them, the manner of their election, and their rights and privileges, except as specified in this Constitution, shall be established in the By-Laws.

ARTICLE IV GOVERNING COUNCIL COMPOSITION

Section 1. There shall be a Governing Council which shall consist of:

(a) The officers of the Association and the elective members of the Executive Board.

(b) The Chairman, Vice-Chairman, and Secretary of each Section, and the elective members of the Council of the Health Officers Section.

(c) One representative to be designated by each Affiliated Society.

(d) One representative to be designated by each Regional Branch.

(e) Thirty members of the Council, to be elected by the Fellowship of the Association, for three-year terms, one-third of whose terms shall expire each year. Such members of the Council shall be known as elective Councilors and shall be nominated and elected as provided for in the By-Laws. If an elective Councilor is elected a Section Chairman, Vice-Chairman, or Secretary, or an elective member of the Council of the Health Officers Section, or appointed the representative of an Affiliated Society, or of a Regional Branch, a Councilor to fill such vacancy shall be elected by the Governing Council. All vacancies while in office shall be filled by election for the unexpired term. After two consecutive terms, an elective Councilor shall be ineligible for reëlection to the Council during one Association year.

Section 2. The terms of all Councilors, except the representatives of Affiliated Societies and Regional Branches, shall begin immediately following the adjournment sine die of the Governing Council in existence at the time of their election and shall terminate with the adjournment sine die of the Governing Council at the annual meeting at which their respective terms expire; provided that newly elected Councilors shall have the right to attend meetings of the Council in an advisory capacity as soon as elected.

The terms of the representatives of Affiliated Societies and Regional Branches shall begin and terminate in accordance with the constitutions and by-laws of their respective organizations.

Section 3. The Officers of the Association shall be the Officers of the Council.

Section 4. A Quorum of the Council shall consist of twenty Councilors.

Section 5. Meetings of the Council shall be called by the Executive Secretary at the request of the President, or at the request in writing of any twelve Councilors. In the latter case, the call to the meeting shall be issued at least twenty days in advance of the meeting and shall state the purpose for which it is called.

ARTICLE V GOVERNING COUNCIL FUNCTIONS

The functions of the Governing Council shall be:

Section 1. To establish and amend the By-Laws of the Association.

Section 2. To establish policies for the Association and for the guidance of the Executive Board and the Officers.

Section 3. To consider all resolutions proposed for approval in the name of the Associa-

tion, and to receive and act upon a report from a committee on resolutions appointed annually by the President.

Section 4. To approve all standards promulgated in the name of the Association.

Section 5. To receive at its first session at the time and place of the annual meeting of the Association, a report from the Chairman of the Executive Board in which the work, the accomplishments, and the financial status of the Association during the year preceding such annual meeting shall be reviewed and a statement made of the major activities contemplated for the ensuing year.

Section 6. To establish Sections of the Association; to combine or discontinue them when necessary; to prescribe the qualifications of the members of Section Councils and the chairmen of Section committees; to maintain coördination among Sections; and to formulate general rules governing their policies.

Section 7. To elect the Executive Board, the officers of the Association, with the exception of the Chairman of the Executive Board and the Executive Secretary, to elect Fellows, Honorary Fellows, Life Members, and Affiliated Societies, and to establish Regional Branches.

Section 8. To publish after each of its meetings an abstract of the minutes of such meeting.

ARTICLE VI OFFICERS

The officers of this Association shall be a President, a President-elect, three Vice-Presidents, an Executive Secretary, a Treasurer, and the Chairman of the Executive Board. The officers, with the exception of the Chairman of the Executive Board and the Executive Secretary, shall be elected by written ballot of the Governing Council as provided in this article and in the By-Laws. The President-elect shall serve as such from the close of the annual meetings at which he was elected to the close of the next annual meeting, when he shall automatically become President. As President he shall serve to the close of the next succeeding annual meeting. However, in case of the inability of the President to complete his term for any reason, the President-elect shall at once succeed to the duties of President, filling the unexpired term of his predecessor and his own term consecutively. Other officers, except the Chairman of the Executive Board and the Executive Secretary, shall serve from the close of the annual meeting when elected until the close of the next annual meeting, and all officers shall serve in any case until their successors are elected and qualified. A majority vote of the Councilors voting shall be required to elect, and if no candidate receives a majority vote on the first ballot, the candidate receiving the smallest number of votes shall be dropped after each ballot in succession until a majority vote is obtained. The Chairman of the Executive Board and the Executive Secretary shall be elected by the Executive Board, which Board shall define the duties and authority of these officers, respectively.

ARTICLE VII. EXECUTIVE BOARD

Section 1. There shall be an Executive Board, consisting of the President, the President-elect, the Treasurer, and six members, to be known as the Elective Members, elected for terms of three years each by the Governing Council. The Elective Members shall be at the time of their election past or present members of the Governing Council. The terms of the Elective Members shall begin at the close of the annual meeting at which they are elected and terminate at the end of the annual meeting at the expiration of their respective terms. The terms of two Elective Members shall expire each year in rotation.

Section 2. Acceptance of membership on the Executive Board shall terminate any appointment such Fellow may hold on any of the standing committees of the Association.

Section 3. It shall be the duty of the Executive Board to direct the administrative work of the Association; to act as the Trustee of the Association's properties; to elect the Members and Sustaining Members; and in general to carry out the policies of the Governing Council between meetings of the latter.

It may designate an Assistant Treasurer whose powers shall be limited to the disbursement of funds in accordance with duly authorized budgets for the ordinary conduct of Association business. Such power shall be exercised only during a period when, in the opinion of the Board, an emergency is created due to the absence or disability of the Treasurer. Such Assistant Treasurer may be a Fellow or a corporate fiduciary institution.

In the event of a vacancy in the office of Treasurer, the Executive Board shall have power to elect a Fellow to serve as Treasurer for the unexpired term.

It shall have such further powers and duties as may be prescribed in the By-Laws.

Section 4. A Quorum of the Executive Board shall consist of five members.

ARTICLE VIII AMENDMENTS

This Constitution may be amended by the Fellows of the Association voting thereon in a ballot cast by mail, provided that the specific amendment to be acted upon is published in the official publica-

tion of the Association not less than thirty days prior to the mailing of the ballots to the Fellows by the Administrative Office, and provided further that the amendment has received prior approval by the Governing Council. The closing date for the reception of ballots shall be forty-five days from the date of the mailing of the ballots by the Administrative Office. An amendment shall become effective only upon receiving an affirmative vote on two-thirds of the ballots cast by the Fellows. The President shall designate Tellers to canvass the ballots and to report the result to the Governing Council as provided in the By-Laws.

BY-LAWS

ARTICLE I FELLOWS

Section 1. Professional health workers who have been members of the Association for at least two years, and who are of established professional standing in the field of public health (whether employed by public or private organizations or in independent private practice) shall be eligible for election as Fellows, provided that the applicant shall have reached his thirtieth birthday at the time application for Fellowship is made and subject to the further conditions of this Article.

Section 2. The following persons shall be considered to have an established professional standing in public health for this purpose:

(a) A person who has rendered acceptable service for two or more years in a responsible public health position and who has been awarded in course a degree of Doctor of Public Health, Doctor of Science in Public Health, Doctor of Philosophy in Public Health, Doctor of Medicine with at least one year of graduate study in public health in a university, Master of Public Health, Diploma in Public Health or other equivalent degrees, according to standards approved by the Executive Board of the American Public Health Association.

(b) A person who has been awarded in course an academic or professional degree involving training in public health and who has been regularly engaged in health work for at least five years, having rendered meritorious service as a health officer or in responsible charge of work in either a public or private health agency.

(c) A person who has done notable original work in public health or preventive medicine of a character to give him a recognized standing.

(d) A person regularly engaged in health work for at least five years, who has given evidence of special proficiency, who has attained a recognized standing.

(e) A teacher of public health or one of its constituent sciences who has attained distinction as an expounder of the principles of public health or its constituent sciences. Such a teacher shall have had at least five years' experience as a teacher of public health subjects. Any years of experience as defined in paragraphs (b) and (d) that the applicant may have had shall be considered the equivalent of the same number of years' experience as a "teacher."

(f) A person not covered by the above, who has made substantial contributions to public health work in his chosen branch and who has attained a recognized professional standing.

Section 3. Every application for Fellowship shall be made on an approved form and shall be sponsored by two Fellows of the Association who shall be Fellows of the Section with which affiliation is desired, provided, however, that when affiliation with a Section is not desired, the sponsors may be any two Fellows in good standing in the Association. Fellows without Section affiliation shall be known as unaffiliated Fellows.

Section 4.

(a) When an application has been duly sponsored and otherwise completed, it shall be transmitted to the Administrative Office of the Association, which shall make note thereon of such knowledge as it may have concerning the standing of the applicant in the Association. The application shall be forwarded by the Administrative Office to the Secretary of the Section in which affiliation is desired for the action of the Section Council, and, when acted upon by the Section Council, he shall return it to the Administrative Office after he shall have endorsed thereon the action of the Section Council. When the application is for unaffiliated Fellowship, the Executive Board of the Association shall act in place of the Section Council. To be eligible for election, individuals applying for Fellowship under the provisions of subsections (a) and (b) of Section 2 of this Article shall require for approval a majority vote of the Section Council or the Executive Board. All other applicants shall require for aproval a two-thirds vote of such Section Council or the Executive Board.

(b) When the application has been approved by the Section Council or the Execu-

tive Board, as above provided, it shall be voted upon by the Committee on Eligibility. Applications requiring a majority vote of the Section Council or Executive Board shall require for approval a majority vote of the Committee on Eligibility. All other applications shall require unanimous approval of the Committee on Eligibility. If approved, as above specified, and provided the name of the applicant shall have been officially published at least fifteen days in advance, the application shall be voted upon by the Governing Council, and if approved by three-fourths of the vote cast, the applicant shall be declared elected a Fellow.

Section 5.

(a) A Fellow may belong to and vote in only one Section, but such affiliation may be transferred to another Section if approved by vote of a majority of the Council of the latter Section. Unaffiliated Fellows may become affiliated with a Section if approved by vote of a majority of the Council of the Section with which affiliation is desired.

(b) Fellows shall have all the rights and privileges provided for Members in addition to those specifically reserved to them by the Constitution and By-Laws.

Section 6. Honorary Fellows may be elected by a three-fourths vote of the Governing Council for distinguished service in public health. Honorary Fellowship shall not confer voting power but Honorary Fellows who have previously been Fellows or members of the Association shall retain all the privileges of Fellowship or membership.

ARTICLE II MEMBERS

Section 1. Persons professionally engaged or interested in public health work shall be eligible for election as members by a three-fourths vote cast by the Executive Board when sponsored by two members or Fellows and after approval by the Committee on Eligibility. They shall be entitled to receive the official journal of the Association, to vote for the officers and members of the Council of the Section with which they are affiliated, and upon all motions and resolutions coming before such Section, to participate generally in its proceedings and to serve on committees, except as provided in the Constitution and By-Laws. A member may belong to and vote in only one Section, but such affiliation may be transferred to another Section if approved by vote of a majority of the Council of the Section to which change is desired. Unaffiliated members may become affiliated with a Section if approved by vote of a majority of the Council of the Section with which affiliation is desired.

Section 2. Individuals or corporations interested in public health may be elected to Sustaining Membership by a three-fourths vote of the Executive Board. Sustaining Members shall be entitled to receive the journal and such other publications of the Association as the Executive Board may designate.

Section 3. Upon the recommendation of the Committee on Eligibility, any individual member or Fellow of the Association may be elected a member for life. The dues for Life Members shall be $200.00 payable within one year after election. Election to this grade shall not affect the privileges held by such an individual as a regularly elected Member or Fellow.

ARTICLE III AFFILIATED SOCIETIES

Section 1. A state or provincial public health association or similar regional society including more or less than a state, primarily composed of professional public health workers and organized for the same general objects as the American Public Health Association, may be elected by a three-fourths vote of the Governing Council as an Affiliated Society, provided that not less than twenty of its active members and at least one-half of its active members are members or Fellows of the American Public Health Association. Not more than one such society shall be admitted from the same area.

Section 2. A society applying for affiliation shall submit a copy of its constitution and by-laws, its last annual budget, a roster of its members, and such other evidences of its qualifications as may be required. It shall submit annually and at other times such reports on its financial standing, membership, and other matters as may be required by the Executive Board of the American Public Health Association.

Section 3. The Committee on Eligibility shall consider all applications for affiliation and report its recommendations to the Governing Council.

ARTICLE IV DUES

Section 1. The following constituents shall be exempt from the payment of annual dues: Honorary Fellows, Life Members, Fellows and Members who have been affiliated with the Association for thirty years or more and who have retired from active duty, and Fellows and Members who have been affiliated with the Association for forty years regardless of retirement. The dues of all other constituents are payable annually in advance.

Section 2. The dues for Members shall be

$7.00, for Fellows $12.00, and for Sustaining Members $100.00 or more.

Section 3. The dues for Affiliated Societies shall be one per cent of their gross annual income, provided that the minimum dues per society shall be $10.00 per year, and provided further that for every Fellow or Member paying annual dues to the American Public Health Association, the Association shall remit to the Affiliated Society of which such person is a member the sum of $1.00 per annum.

ARTICLE V DISCONTINUANCE OF MEMBERSHIP

Section 1. Constituents of any class whose dues are unpaid for six months or more shall be considered not in good standing. Constituents not in good standing shall not be entitled to any of the privileges or powers of membership, Fellowship, or affiliation. Good standing may be resumed upon the payment of all arreas and dues in advance for one year, provided the lapsed period is not greater than one year. The Administrative Office shall notify by registered mail all constituents who have been in arrears for a period of eleven months. The names of constituents in any class whose dues remain unpaid for one year or more and who have been duly notified as above provided shall be presented to the Executive Board which shall order the names of such constituents stricken from the membership roll. Constituents whose names have been stricken from the rolls in this manner may be again admitted in the manner provided for the election of new constituents in the class for which they make application, provided such person or organization complies with the eligibility requirements at the time the new application is made.

Section 2. If, in the opinion of the Executive Board, any member or Fellow of the Association permits the use of his name, or otherwise allows himself to be quoted or used for illustration in the advertising of a commercial product, in such a manner as to reflect discredit upon the Association, his Fellowship or membership in the Association shall thereupon be terminated.

Section 3. Upon the recommendation of the Committee on Eligibility the Governing Council may discontinue the membership, Fellowship or affiliation of any constituent. Three-fourths of the votes cast shall be necessary for such action.

ARTICLE VI PUBLICATIONS

Section 1. All publications of the Association and of its Sections shall be issued under the direction of the Executive Board.

Section 2. The American Journal of Public Health shall be the official journal of the Association. The Executive Board shall appoint a Managing Editor of the official journal and an Editorial Board of not less than five members to serve at the pleasure of the Executive Board. All papers and reports for the annual meetings are to be accepted with the understanding that they shall be the property of the Association for publication, unless this right is waived by the Managing Editor.

ARTICLE VII ELECTIVE COUNCILORS

The Elective Members of the Governing Council shall be nominated and elected according to the following procedure and schedule. The times designated for the several steps shall date from the first day of the next annual meeting as designated by the Executive Board.

Section 1. There shall be a Nominating Committee composed of one Fellow elected by each Section at the preceding annual meeting, and an additional Fellow designated by the Executive Board, the latter serving as Chairman. This Committee shall present to the Administrative Office not less than six months before the annual meeting the names of at least twenty and not more than thirty Fellows of the Association selected with due regard to geographical and membership considerations as nominees for the Governing Council.

Section 2. The Administrative Office shall publish to the Fellowship not less than five months before the annual meeting the nominees selected by the Nominating Committee and at the same time shall announce the date on which the official ballots will be mailed to the Fellows.

Section 3. Upon the petition of twenty-five Fellows the Nominating Committee shall add the name of any Fellow to the nominees selected by it, provided such petition is received not less than three months before the annual meeting.

Section 4. Not less than two months previous to the annual meeting the Administrative Office shall mail to each Fellow entitled to vote an official ballot upon which the names of all nominees shall appear in order determined by lot. Accompanying each ballot shall be two envelopes, one marked "Ballot Envelope," into which the voter shall place his marked ballot. This envelope shall then be sealed and placed in the outer envelope which shall bear the signature and address of the voter.

Section 5. Only ballots received not later than one month before the annual meeting

shall be accepted and counted. No duplicate ballots shall be furnished to any Fellow.

Section 6. All ballots received prior to the closing date shall be placed in the custody of the Tellers unopened.

Section 7. The Fellows receiving the highest number of votes on a written ballot cast by the Fellows shall be declared elected to fill vacancies which will exist at the adjournment sine die of the Governing Council at the next annual meeting. Should two or more candidates receive the same number of votes, the Governing Council shall, when necessary, determine the order of precedence of such candidates.

Section 8. Not less than sixty days before the annual meeting the President shall appoint three Tellers from among the members of the Governing Council, one of whom shall be designated as Chairman. The Tellers shall canvass the vote on elective Councilors and on any amendment to the Constitution and shall report the result of all ballots cast to the Governing Council at its first meeting during the annual meeting.

ARTICLE VIII EXECUTIVE BOARD

Section 1. The Executive Board shall elect from its own membership a Chairman who shall serve in that capacity for such term as the Executive Board shall determine. It shall also designate such other officers of the Board as it may require for the conduct of its business.

Section 2. If a vacancy among the Elective Members of the Executive Board shall occur after the annual meeting, the President shall designate a nominating committee from the Governing Council. Such committee shall nominate not less than three candidates for the vacancy, from among whom the candidate receiving the highest number of votes of the Governing Council in a mail ballot shall be declared elected to the Executive Board to fill the vacancy.

Section 3. In addition to those prescribed in the Constitution and in these By-Laws, the Executive Board shall have the following powers and duties:

(a) To plan methods for the procurement of funds.

(b) To approve the budgets for the Association's work.

(c) To conform to the policies of the Governing Council in the conduct of its work.

(d) To designate the chairmen of the standing committees, to appoint their members unless otherwise provided by these By-Laws. To authorize the establishment of all other Association committees and confirm the appointment of their members.

(e) To transmit a report of its proceedings and transactions to the Governing Council at least thirty days before each annual meeting.

Section 4. After two consecutive terms of three years an elective member of the Executive Board, except one serving as chairman, shall be ineligible for reëlection during one Association year.

ARTICLE IX NOMINATION OF OFFICERS

The officers elected by the Governing Council shall be nominated from the floor by that body.

ARTICLE X STANDING AND SPECIAL COMMITTEES

Section 1. There shall be four standing committees of the Association as follows:

(a) Committee on Eligibility.

(b) Committee on Administrative Practice.

(c) Committee on Research and Standards.

(d) Committee on Professional Education.

Section 2. Each standing committee shall designate from among its membership such officers as it may require for the conduct of its business and shall control its policies within the limitations prescribed by the Governing Council and the Executive Board. The Executive Secretary shall be a member, ex-officio, and serve as secretary of each standing committee.

Section 3.

(a) The Committee on Eligibility shall consist of one Fellow to be elected by each Section and an additional Fellow elected by the Executive Board who shall serve as Chairman. Members shall serve for a term of two years.

(b) This committee shall pass upon the eligibility of Fellows, members and other constituents in accordance with the provisions of the By-Laws.

Section 4.

(a) The Committee on Administrative Practice shall consist of fifteen Fellows, twelve of whom shall be designated by the Executive Board to serve for a term of four years, the terms of three members expiring each year, and three members elected by and from the Fellows affiliated with the Health Officers Section, one of whom shall be elected annually for a term of three years. Following the adoption of this amendment one member shall be elected to serve for one year, one for two years and one for three years.

(b) This committee shall engage in the collection of information regarding current public health practices and analyze the material obtained to derive standards of organization and achievement. The findings and standards

may be made available to public health workers through publications, information and field service under such conditions as the committee may establish. No standards shall be promulgated as the official and authorized judgment of the Association except with the approval of the Governing Council.

Section 5.

(a) The Committee on Research and Standards shall consist of fifteen Fellows representative of the various Sections of the Association appointed by the Executive Board. Members shall serve for a term of three years, the terms of five members expiring each year.

(b) This committee shall be responsible for initiating, conducting, promoting, coördinating and reviewing research and development of standards in the technical branches of public health. This committee shall also be charged with the duty of reviewing from time to time standards already established. No standards shall be promulgated as the official and authorized judgment of the Association except with the approval of the Governing Council.

Section 6.

(a) The Committee on Professional Education shall consist of twelve Fellows appointed by the Executive Board. Members shall serve for a term of three years, the terms of four members expiring each year.

(b) This committee shall be responsible for carrying out research and the development of standards for professional education and training in public health work and shall perform such other functions as may be delegated to the committee by the Governing Council with the view of maintaining professional qualifications of high standard. No standards shall be promulgated as the official and authorized judgment of the Association except with the approval of the Governing Council.

Section 7. Unless otherwise provided in these By-Laws, all other Association Committees shall be authorized and appointed by the Executive Board and the appointments of their members shall expire at the next annual meeting.

ARTICLE XI SECTIONS

Section 1. The Executive Board shall approve rules and regulations relating to the government of the Sections, and to the appointment of administrative committees. Each Section shall elect its own officers and shall name its respective Section committees. The right to hold office or to serve as a member of a Section Council or as chairman of a committee in a Section shall be limited to the Fellows affiliated with such Section.

Section 2.

(a) The Section Chairman, with the advice of the Section Council, shall appoint a Committee on Nominations from the Fellows affiliated with the Section at least fifteen days before each annual meeting. The Section Secretary shall be a member of such committee.

(b) The names of the members of the Committee on Nominations shall be announced at the first meeting of the Section at each annual meeting of the Association. The Committee on Nominations shall present at the second meeting of the Section a list of nominees for the Section officers, and for membership in the Section Council; provided that if the name of any Fellow be transmitted to the Nominating Committee over the signature of ten Fellows of the Section prior to the second meeting of the Section, the Nominating Committee shall add the name of such Fellow to its own list of nominees.

Section 3. The officers of each Section shall be a Chairman, a Vice-Chairman, and a Secretary, who shall be the representatives of the Section to the Governing Council of the Association, except as provided in the Constitution.

Section 4. New terms shall begin and old terms shall expire at the end of annual meetings. After five consecutive years in any elective Section office, except that of Secretary, a member shall be ineligible to reëlection to that office during one Association year.

Section 5. The Chairman, or in his absence the Vice-Chairman, shall preside at meetings of the Section.

Section 6. The Secretary shall prepare the scientific program of the Section for the annual meeting, subject to the recommendations of the Section Council, and shall submit same to the Administrative Office. He shall keep the minutes and other records of the Section, and shall transmit to the Executive Secretary of the Association a copy of the minutes of both the business and scientific sessions as soon as practicable after the close of the annual meeting of the Association. When unable to be present at meetings, he shall thoroughly instruct a substitute as far in advance of the meeting as possible.

Section 7. There shall be a Section Council composed of the three officers of the Section and five members, to be known as the elective members, each of whom shall be elected for a term of five years; provided that when a Section is first established one member shall be elected to serve for one year, one for two, one for three, one for four, and one for five years.

Section 8. The duties of the Section Council shall be:

(a) To recommend papers, and to make general recommendations in relation to the annual meeting program.

(b) To advise on Section membership and on Section policies.

(c) To submit annually to the Governing Council through the Executive Board a report of the transactions of the Section.

(d) To report annually to the Governing Council through the Executive Board on the plans, scope and policy of the Section during the succeeding year.

(e) To formulate rules of procedure for the Section.

(f) To consider and transmit to the Governing Council resolutions originating in the Section. Only resolutions approved by the Governing Council shall be published as representing the policy of the Association.

(g) To advise on the publication of papers and reports presented at the Section meetings.

(h) To advise with respect to the appointment of technical committees, subcommittees, or Section representatives on committees of the Association.

ARTICLE XII FINANCES

All remittances to the Association shall be deposited to the account of the Treasurer. The Treasurer shall be custodian of investments of the Association and shall disburse funds in accordance with duly authorized vouchers. With the approval of the Executive Board he may establish a drawing account for the Executive Secretary, who shall send to members of the Executive Board a financial summary of receipts and disbursements each month. Once each month, or oftener if called for, he shall also forward to the Treasurer and to the Chairman of the Executive Board an itemized statement of all expenditures. The Executive Secretary, the Treasurer and the Assistant Treasurer shall be bonded at the expense of the Association in an amount to be determined by the Executive Board. The books of the Association shall be audited annually by certified public accountants to be appointed by the Executive Board.

ARTICLE XIII MEETINGS OF THE ASSOCIATION

There shall be one general meeting of the Association, to be known as the annual meeting which shall be held each year at a place selected by the Governing Council at a time designated by the Executive Board provided, however, that the Governing Council may determine by voting at a regular meeting or by ballots cast by mail, that the annual meeting for a stated calendar year shall not be held; and provided further, that in case of great emergency the Executive Board may defer any annual meeting for not to exceed three months. Special meetings of the Association may be called by a majority vote of the Governing Council, the Executive Board, or the Association. In all proceedings of the Association, *Robert's Rules of Order* shall be official.

ARTICLE XIV AMENDMENTS

These By-Laws may be amended by a two-thirds vote of those voting on the Governing Council during the annual meeting, provided that twenty-four hours prior written notice thereof has been given. The By-laws may further be amended by a two-thirds vote of those voting at any meeting of the Governing Council called for the purpose, provided that notice thereof shall have been given at least fifteen days prior to such meeting.

SCIENTIFIC EXHIBIT CITATIONS BOSTON ANNUAL MEETING

At the 76th Annual Meeting in Boston 43 exhibitors participated in the Scientific Exhibit presented under the auspices of the Scientific Exhibits Committee, of which Franklin M. Foote, M.D., is *Chairman.* The members are:

Paul H. Brown, M.D.
Homer N. Calver
Vivian Drenckhahn
Francis B. Elder
Horace Hughes
S. S. Litson
Willimina Rayne Walsh

Members of the committee judged the exhibits using the following criteria:

1. Obvious public interest and attraction
2. New contribution to public health and toward better understanding
3. Clarity of presentation
4. The factor of expense of production—an inexpensively constructed exhibit, for example, that tells a good story.
5. Appropriateness for the audience

While the committee was unanimous in acclaiming the high quality of all the exhibits, it cited six outstanding exhibits as follows:

1. An Exhibit Is an Exhibit Is an Exhibit—But What Is That?—Henriette Strauss
2. Boston Health Department
3. Brookline Health Department
4. Iowa State Department of Health
5. National Tuberculosis Association
6. U. S. Public Health Service

The committee ruled out of consideration for citation exhibits sponsored by the Association itself, but declared that two were deserving of special mention. They were:

1. The Merit System
2. Health Education and Publicity Headquarters

The Association acknowledges with deep appreciation its indebtedness to its Sustaining Members whose annual dues help support the Association's general program

Charles E. Smith, M.D. (1950)
Carl C. Dauer, M.D. (1949)

Food and Nutrition Section

(Organized 1917)

Paul S. Prickett, Ph.D., *Chairman,* Mead Johnson & Co., Evansville, Ind.
Margaret C. Moore, *Vice-Chairman,* State Dept. of Health, New Orleans, La.
Alice H. Smith, *Secretary,* State Dept. of Health, Lansing, Mich.
Frances MacKinnon (1953)
Lloyd B. Jensen, Ph.D. (1952)
Marietta Eichelberger, Ph.D. (1951)
William H. Sebrell, Jr., M.D. (1950)
Donald K. Tressler, Ph.D. (1949)

Health Officers Section

(Organized 1908)

Stanford F. Farnsworth, M.D., *Chairman,* City Health Dept., Oakland, Calif.
John M. Whitney, M.D., *Vice-Chairman,* American National Red Cross, Washington, D. C.
Joseph G. Molner, M.D., *Secretary,* Department of Health, Detroit, Mich.
C. Howe Eller, M.D. (1953)
Richard F. Boyd, M.D. (1952)
Carl N. Neupert, M.D. (1951)
Emil E. Palmquist, M.D. (1950)
Joseph H. Kinnaman, M.D. (1949)

Industrial Hygiene Section

(Organized 1914)

William G. Fredrick, Sc.D., *Chairman,* Department of Health, Detroit, Mich.
Leonard Greenburg, M.D., *Vice-Chairman,* State Dept. of Labor, New York, N. Y.
Richard T. Page, *Secretary,* Department of Health, Kansas City, Mo.
Carl M. Peterson, M.D. (1953)
Helmuth H. Schrenk, Ph.D. (1952)
T. Lyle Hazlett, M.D. (1951)
Kenneth M. Morse (1950)
Herbert G. Dyktor (1949)

Laboratory Section

(Organized 1899)

Howard J. Shaughnessy, Ph.D., *Chairman,* State Dept. of Health, Chicago, Ill.
Geoffrey Edsall, M. D., *Vice-Chairman,* Div. of Biologic Labs., State Dept. of Health, Jamaica Plain, Mass.
Albert H. Harris, 2nd, M.D., *Secretary,* State Dept. of Health, Albany, N. Y.
Edmund K. Kline, Dr.P.H. (1953)

Sara E. Branham, M.D. (1952)
Walter L. Mallmann, Ph.D. (1951)
John F. Mahoney, M.D. (1950)
C. A. Perry, Sc.D. (1949)

Maternal and Child Health Section

(Organized 1921)

Sarah S. Deitrick, M.D., *Chairman,* U. S. Children's Bureau, Washington, D. C.
Samuel B. Kirkwood, M.D., *Vice-Chairman,* Harvard School of Public Health, Boston, Mass.
Edward Davens, M.D., *Secretary,* State Dept. of Health, Baltimore, Md.
Edward R. Schlesinger, M.D. (1953)
Louis Spekter, M.D. (1952)
Francis V. Corrigan, M.D. (1951)
Paul R. Ensign, M.D. (1950)
Ruth J. Raattama, M.D. (1949)

Medical Care Section

(Organized 1948)

Edward S. Rogers, M.D., *Chairman,* University of California, Berkeley, Calif.
Edwin L. Crosby, M.D., *Vice-Chairman,* Johns Hopkins Hospital, Baltimore, Md.
Milton Terris, M.D., *Secretary,* P. O. Box 5998, Bethesda, Md.
Dean A. Clark, M.D.
Edwin F. Daily, M.D.
Herbert L. Lombard, M.D.
Ellen C. Potter, M.D.
Marian G. Randall, R.N.

Public Health Education Section

(Organized 1922)

A. Helen Martikainen, *Chairman,* State Board of Health, Raleigh, N. C.
Bess Exton, *Vice-Chairman,* 3704 Prestwick Drive, Los Angeles, Calif.
Donald A. Dukelow, M.D., *Secretary,* American Medical Association, Chicago, Ill.
Granville W. Larimore, M.D. (1953)
Mabel E. Rugen, Ph.D. (1952)
Eunice N. Tyler, Ph.D. (1951)
Lewis C. Robbins, M.D. (1950)
Howard W. Lundy, Dr.P.H. (1949)

Public Health Nursing Section

(Organized 1923)

Ruth Freeman, R.N., *Chairman,* American National Red Cross, Washington, D. C.
Margaret S. Taylor, R.N., *Vice-Chairman,* University of Minnesota, Minneapolis, Minn.
Margaret L. Shetland, R.N., *Secretary,* State Dept. of Health, Lansing, Mich.
Marion Ferguson, R.N. (1953)
Mary C. Connor, R.N. (1952)
Helene B. Buker, R.N. (1951)
Elizabeth L. Smellie, R.N. (1950)
Marion H. Douglas, R.N. (1949)

School Health Section

(Organized 1942)

Warren H. Southworth, Dr.P.H., *Chairman,* University of Wisconsin, Madison, Wis.
Marjorie L. Craig, *Vice-Chairman,* Metropolitan Life Insurance Co., New York, N. Y.
S. S. Lifson, *Secretary,* American Heart Assn., New York, N. Y.
William L. Hughes, Ph.D. (1953)
Dorothy B. Nyswander, Ph.D. (1952)
Leona Baumgartner, M.D. (1951)
A. O. DeWeese, M.D. (1950)
C. L. Outland, M.D. (1949)

Statistics Section

(Organized 1908)

Forrest E. Linder, Ph.D., *Chairman,* United Nations, Lake Success, N. Y.
Elizabeth Parkhurst, *Vice-Chairman,* State Dept. of Health, Albany, N. Y.
Clara E. Councell, Ph.D., *Secretary,* U. S. Children's Bureau, Washington, D. C.
Paul Parrot, M.D. (1953)
Iwao M. Moriyama, Ph.D. (1952)
Paul M. Densen, D.Sc. (1951)
Robert G. Webster (1950)
Alan E. Treloar, Ph.D. (1949)

American Public Health Association

COMMITTEES

1948–1949

THE ASSOCIATION COMMITTEE LISTS

These pages again bring to the readers the lists of Association officers and Committee members. Once again they make a goodly company representing altogether more than 150 committees and other councils, a capable and loyal group of workers.

A certain proportion of the names of those formerly carried on such lists do not appear here. They have the Association's thanks for work well done in other years and for the fine spirit in which they have recognized the fact that, for the sake of the Association and its future effectiveness, leadership must be shared and leaders constantly developed through the assumption of responsibility. Our Association is stronger today because leaders periodically have stepped aside in order that others may step forward to acquire such knowledge as they themselves have gained.

Change in leadership is an accepted policy in the Association. Such a professional society is never strong if an informed few lead many uninformed though loyal followers. A strong association is composed of leaders many of whom could at any time take their turn and lead.

As we gratefully acknowledge the debt to those who have rendered their service as they carried their responsibilities of office, we turn with hope and expectation of other achievements to the men and women who are now to lead.

Committee on Administrative Practice

Wilton L. Halverson, M.D., *Chairman,* State Department of Public Health, San Francisco, Calif. (1951)
Haven Emerson, M.D., *Vice-Chairman* (1949)
Reginald M. Atwater, M.D., *Secretary,* 1790 Broadway, New York, N. Y.
Gregoire F. Amyot, M.D. (1949) Representing the Health Officers Section
Richard F. Boyd, M.D. (1949)
George D. W. Cameron, M.D. (1952)
Harry L. Chant, M.D. (1950)
Dean A. Clark, M.D. (1952)
George B. Darling, Dr.P.H. (1950)
Robert E. Fox, M.D. (1951) Representing the Health Officers Section
Thomas Francis, Jr., M.D., Chairman, Committee on Research and Standards (*ex officio*)
Ira V. Hiscock, Sc.D. (1951)
Robert H. Hutcheson, M.D. (1952)
Marie L. Johnson, R.N. (1951)
Joseph H. Kinnaman, M.D. (1950) Representing the Health Officers Section
Joseph W. Mountin, M.D. (1950)
H. A. Whittaker (1949)

Consultants:
Clarence E. Scamman, M.D.
Henry F. Vaughan, Dr.P.H.
C.-E. A. Winslow, Dr.P.H.

Staff
Roscoe P. Kandle, M.D., *Field Director*
Robert E. Rothermel, M.D., *Assistant Field Director*
Edith M. Boyd, *Associate Secretary*
Erminie C. Lacey, *Statistical Analyst*

Executive Committee
Wilton L. Halverson, M.D., *Chairman,* State Department of Public Health, San Francisco, Calif.
Reginald M. Atwater, M.D.
George B. Darling, Dr.P.H.
Haven Emerson, M.D.
Joseph W. Mountin, M.D.

Subcommittee on Accident Prevention

Donald B. Armstrong, M.D., *Chairman,* One Madison Avenue, New York, N. Y.
W. W. Bauer, M.D.
I. J. Brightman, M.D.
Albert L. Chapman, M.D.
Halbert L. Dunn, M.D., Representing Statistics Section
Thomas Fansler
John E. Gordon, M.D.
H. E. Kleinschmidt, M.D.
Elisabeth C. Phillips, R.N.
Edward S. Rogers, M.D.
Milton J. E. Senn, M.D.
Ernest L. Stebbins, M.D.
Paul F. Stricker

Subcommittee on Evaluation of Administrative Practices

Haven Emerson, M.D., *Chairman,* 156 East 79th Street, New York, N. Y.
Dwight M. Bissell, M.D.
Bruce H. Douglas, M.D.
Joseph H. Kinnaman, M.D.
Joseph W. Mountin, M.D.

Diphtheria

W. E. Bunney, Ph.D., *Secretary,* 745 Fifth Avenue, New York, N. Y.
James A. Doull, M.D.
Donald T. Fraser, M.B., D.P.H.
Martin Frobisher, Jr., Sc.D.
D. Gordon Gill, M.B., D.P.H.
G. Foard McGinnes, M.D.
Erich Seligmann, M.D.
Ernest L. Stebbins, M.D.
John T. Tripp, Ph.D.
V. K. Volk, M.D.

Endemic Goiter

O. P. Kimball, M.D., *Secretary,* Hanna Building, Cleveland, Ohio
George M. Curtis, M.D.
E. B. Hart, Ph.D.
Roy Donaldson McClure, M.D.,
B. E. Brush, M.D., *Alternate*
William H. Sebrell, Jr., M.D., *Referee*
Harry A. Towsley, M.D.
W. G. Wilcox, Ph.D.

Consultants:

David Marine, M.D.
E. M. Nelson, Ph.D.
Russell M. Wilder, M.D.

Hemolytic Streptococcal Infections

Franklin H. Top, M.D., *Secretary,* Herman Kiefer Hospital, Detroit, Mich.
Gaylord W. Anderson, M.D.
Donald T. Fraser, M.B., D.P.H.
John R. Paul, M.D.
Milton V. Veldee, M.D.

Multiple Antigens

W. E. Bunney, Ph.D., *Secretary,* 745 Fifth Ave., New York, N. Y.
Donald T. Fraser, M.B., D.P.H.
Pearl L. Kendrick, Sc.D.
Franklin H. Top, M.D.
Milton V. Veldee, M.D.
V. K. Volk, M.D.

Tuberculosis Control Procedures

Bruce H. Douglas, M.D., *Secretary,* Commissioner of Health, Detroit, Mich.
Robert J. Anderson, M.D.
Mary V. Dempsey
Herbert R. Edwards, M.D.
Esmond R. Long, M.D.
James E. Perkins, M.D.
Robert E. Plunkett, M.D.
Marion W. Sheahan, R.N.
George J. Wherrett, M.D.

Typhoid Fever

Roy F. Feemster, M.D., *Secretary,* Room 519, State House, Boston, Mass.
Gaylord W. Anderson, M.D.
Adrian R. Foley, M.D.
A. L. Gray, M.D.
Albert V. Hardy, M.D.
Hollis S. Ingraham, M.D.
Kenneth F. Maxcy, M.D., *Referee*

Subcommittee on Local Health Units

Haven Emerson, M.D., *Chairman,* 156 East 79th Street, New York, N. Y.
Richard F. Boyd, M.D.
Leroy E. Burney, M.D.
A. J. Chesley, M.D.
Alfred L. Frechette, M.D.
D. Gordon Gill, M.B., D.P.H.
J. Roy Hege, M.D.
Robert H. Hutcheson, M.D.
Matthew R. Kinde, M.D., *Consultant*
Fred Mayes, M.D.
Joseph W. Mountin, M.D.
Nathan Sinai, Dr.P.H.
Bruce Underwood, M.D.

Subcommittee on Medical Care

Dean A. Clark, M.D., *Chairman,* 425 Avenue of the Americas, New York, N. Y.
Edwin F. Daily, M.D.
V. L. Ellicott, M.D.
Isidore S. Falk, Ph.D.
Vlado A. Getting, M.D.

Friend Lee Mickle, Sc.D. (1949)
John F. Norton, Ph.D. (1949)
Helmuth H. Schrenk, Ph.D. (1950)
Fred W. Tanner, Ph.D. (1950)

Consultant:
Abel Wolman, Dr.Eng.

Staff
Francis B. Elder, *Associate Secretary*

Coördinating Committee on Laboratory Methods

Friend Lee Mickle, Sc.D., *Chairman,* State Department of Health, Hartford, Conn.
Reginald M. Atwater, M.D., *Secretary*

Francis B. Elder, *Associate Secretary*
Roy F. Feemster, M.D.
Lloyd B. Jensen, Ph.D.
Edmund K. Kline, Dr.P.H.
Pearl L. Kendrick, Sc.D.
Seward E. Miller, M.D.
Ralph S. Muckenfuss, M.D.
Walter D. Tiedeman

Subcommittee on Diagnostic Procedures and Reagents

Ralph S. Muckenfuss, M.D. (Lab.), *Chairman,* City Dept. of Health, New York, N. Y.
Meningococcus—S. E. Branham, Ph.D. (Lab.)
Tularemia—G. D. Brigham, Ph.D. (Lab.)
Laboratory Diagnosis of Helminths and Protozoa—H. W. Brown, M.D. (Ep.)
Gonococcus—C. M. Carpenter, M.D. (Lab.)
Eberthella typhosa and Other Bacillary Incitants of Enteric Disease—M. B. Coleman (Lab.)
Pathogenic Fungi—Norman F. Conant, M.D.
Bacterial Food Poisoning—G. M. Dack, Ph.D. (Lab.)
Determination Levels of Antibiotics and Response to Bacteria—Carolyn Falk (Lab.)
Leptospira Infections—Abram B. Stravitsky, V.M.D.
Diphtheria—Martin Frobisher, Jr., Sc.D. (Lab.)
Pneumococcus — Kenneth Goodner, Ph.D. (Lab.)
Anthrax-Glanders — William A. Hagan, D.V.M. (Lab.)
Hemophilus Pertussis—Pearl L. Kendrick, Sc.D. (Lab.)
Rh Testing—Philip Levine, M.D. (M&CH)
Streptococcus — G. M. Mackenzie, M.D. (Med. C.)
Tubercle Bacillus—Martin Cummings, M.D. (Ep.)
Serology of Syphilis—John F. Mahoney, M.D. (Lab.)
Chancroid and Granuloma Inguinale—E. S. Sanderson, M.D. (Lab.)
The Cholera Vibrio—C. V. Seastone, M.D.
Malaria Parasite of Man—Aimee Wilcox (Lab.)
Blood Cultures—Caspar G. Burn, M.D. (Lab.)
Infectious Mononucleosis—Charles A. Stuart, Ph.D. (Lab.)
Culture Media—Major Philip Carlquist (Lab.)
Trichinosis—Howard B. Shookhoff, M.D. (Ep.)
Undulant Fever—Earle K. Borman and D. Evelyn West (Lab.)

Subcommittee on Enteric Phage Typing

Pearl L. Kendrick, Sc.D. (Lab.)—*Chairman,* State Dept. of Health, Grand Rapids, Mich.
William W. Ferguson, Ph.D. (Lab.), *Secretary,* State Dept. of Health, Lansing, Mich.
Howard L. Bodily, Ph.D. (Lab.)
Earle K. Borman
Eina M. Clark (Lab.)
Marion B. Coleman (Lab.)
Jean-Marc Desranleau (Lab.)
Philip R. Edwards, Ph.D.
A. S. Lazarus, Ph.D. (Lab.)

Subcommittee on Laboratory Examination of Shellfish

James J. Gibbard (Lab.)—*Chairman,* Dept. of National Health and Welfare, Ottawa, Ontario, Canada
Cornelius B. Kelly, Jr. (Lab.)—*Secretary,* State of N. Y. Conservation Dept., Bureau of Marine Fisheries, Freeport, Long Island, N. Y.
Victor H. Bertullo, D.V.M. (Lab.)
Chester T. Butterfield (Lab.)
Dorothy Phelps
Charles E. Renn, Ph.D. (Eng.)
Glenn G. Slocum, Ph.D. (F.&N.)
Leon Buchbinder, Ph.D. (Lab.)
Elsie Wattie

Subcommittee on Methods for the Microbiological Examination of Foods

Harry E. Goresline, Ph.D. (F.&N.) *Chairman,* 402 Hamilton Ave., Silver Spring, Md.
M. Thomas Bartram, Ph.D. (F.&N.)
James A. Berry, (F.&N.)
Edwin J. Cameron, Ph.D. (F.&N.)
John H. Etchells, Ph.D. (F.&N.)
F. W. Fabian, Ph.D. (F.&N.)
Harlow H. Hall, Ph.D. (F.&N.)
Matthew E. Highlands (F.&N.)
Lloyd B. Jensen, Ph.D. (F.&N.)
C. K. Johns, Ph.D. (Lab.)
Carl S. Pederson, Ph.D. (F.&N.)
Paul S. Prickett, Ph.D. (F.&N.)
B. E. Proctor, Ph.D. (F.&N.)
Archie H. Robertson, Ph.D. (Lab.)
John M. Sharf, Ph.D. (F.&N.)
Glenn G. Slocum, Ph.D. (F.&N.)

Subcommittee on Reference Methods for Syphilis Serology

John F. Mahoney, M.D. (Lab.), *Chairman,* V.D. Research Laboratory, U. S. Marine Hospital, Staten Island, N. Y.

Earle K. Borman
F. R. Hassler, M.D. (Lab.)
Ad Harris (Lab.)
Victor N. Tompkins, M.D. (Lab.)
E. L. Webb (Lab.)
Daniel Widelock, Ph.D. (Lab.)
R. H. Allen, M.D.

Subcommittee on Standard Methods for the Examination of Dairy Products

Archie H. Robertson, Ph.D. (Lab.), *Chairman,* Dept. of Agriculture and Markets, Albany, N. Y.
Luther A. Black, Ph.D. (Lab.)
Robert S. Breed, Ph.D. (Lab.)
Angel de la Garza Brito, M.D. (H.O.)
Raoul F. Cowley (F.&N.)
A. W. Fuchs, C.E. (Eng.)
James Gibbard (Lab.)

Referees:

Luther A. Black, Ph.D. (Lab.)—Comparison of Methods for Determining Bacterial Content
William A. Queen (F.&N.)—Chemical Methods for Examining Dairy Products
S. R. Damon, Ph.D. (Lab.)—Comparative Tests of Agar Media for Standard Plate Counts
A. W. Fuchs, C.E. (Eng.)—Coördination of Milk Ordinance and Laboratory Work
Raymond V. Stone, D.V.M. (Lab.)—Laboratory Equipment
Jacques Archambault, Sc.D. (Lab.)—Method for Detecting Organisms of the Coliform Group
Mac H. McCrady (Lab.)—Methods for Isolating Specific Types of Bacteria
C. A. Abele, Ch.E. (Eng.)—Methylene Blue Reduction Method
C. K. Johns, Ph.D. (Lab.)—Resazurin Reduction Method
E. H. Parfitt, Ph.D. (F.&N.)—Sediment Test
Walter D. Tiedeman (Eng.)—Tests for Sterility of Dairy Utensils
Leon Buchbinder, Ph.D. (Lab.)—Microbiological Examination of Frozen Desserts
F. W. Fabian, Ph.D. (F.&N.)—Microbiological Examination of Frozen Dessert Ingredients
J. H. Shrader, Ph.D. (F.&N.)—Chemical Analysis of Frozen Desserts and Ingredients

Associate Referees:

I. F. Huddleson, Ph.D.—Methods for Detecting Brucella Species
William A. Hagan, D.V.M. (Lab.)—Methods for Detecting Tubercle Bacilli
George J. Hucker, Ph.D. (F.&N.)—Methods for Identifying Streptococci
L. H. Burgwald (Lab.)—Phosphatase Test
E. H. Parfitt, Ph.D. (F.&N.)—Microbiological Examination of Condensed and Evaporated Milk
Paul S. Prickett, Ph.D. (F.&N.)—Microbiological Examination of Dried Milk
M. Thomas Bartram, Ph.D. (F.&N.)—Microbiological Examination of Eggs
M. J. Prucha, Ph.D. (Lab.)—Microbiological Examination of Flavors, Colors, Fruits and Nuts
H. H. Hall (F. & N.)—Microbiological Examination of Sugar
(To be appointed)—Microbiological Examination of Stabilizers

Subcommittee on Methylene Blue and Resazurin Reduction Methods

C. A. Abele, Ch.E. (Eng.)—*Chairman,* 53 West Jackson Boulevard, Chicago, Ill.
C. K. Johns, Ph.D. (Lab.)
E. H. Parfitt, Ph.D. (F.&N.)

Subcommittee on Sediment Testing

E. H. Parfitt, Ph.D. (F.&N.)—*Chairman,* 307 No. Michigan Ave., Chicago, Ill.
K. G. Weckel, Ph.D. (F.&N.)
Curtis R. Joiner

Subcommittee on the Examination of Frozen Desserts

Leon Buchbinder, Ph.D. (Lab.)—*Chairman,* City Health Dept., 125 Worth St., New York, N. Y.
W. C. Bartsch (Lab.)
W. A. Cordes

Subcommittee on Standard Methods for the Examination of Water and Sewage

F. Wellington Gilcreas (Lab.)—*Chairman,* State Dept. of Health, Albany, N. Y.
Raymond J. Faust (Eng.)
Charles A. Hunter, Ph.D. (Lab.)
Joseph McCarthy (Lab.)
Ralph E. Noble (Lab.)
Theodore A. Olson (Lab.)
J. Raymond Sanborn, Ph.D. (F.&N.)
Charles Spangler (Eng.)
Charles A. Stuart, Ph.D. (Lab.)
Adviser: W. L. Mallmann, Ph.D. (Lab.)

Subcommittee on Diagnostic Procedures for Virus and Rickettsial Diseases

Thomas Francis, Jr., M.D. (Ep.) *Chairman,* School of Public Health, Ann Arbor, Mich.
John C. Bugher, M.D. (Un.)
John F. Enders, Ph.D. (Lab.)
Alto E. Feller, M.D. (Ep.)
William McD. Hammon, M.D. (Ep.)
George K. Hirst, M.D.
Harold V. Johnson, M.D. (Lab.)
Karl F. Meyer, M.D. (Ep.)

Robert F. Parker, M.D.
John R. Paul, M.D. (Ep.)
Geoffrey Rake, M.D.
Albert S. Sabin, M.D.
Thomas F. Sellers, M.D. (Lab.)
T. F. McNair Scott, M.D.
Joseph E. Smadel, M.D. (Lab.)
Phillips Tygeson, M.D.
Norman H. Topping, M.D. (Ep.)

Subcommittee on Diagnostic and Therapeutic Biological Products

John T. Tripp, Ph.D., *Chairman,* State Dept. of Health, Lansing, Mich.
Geoffrey Edsall, M.D. (Lab.)
Howard J. Shaughnessy, Ph.D. (Lab.)
Milton V. Veldee, M.D. (Ep.)

Joint Committee on Research Problems in Illumination (Joint with Illuminating Engineering Society)

A.P.H.A.
Leonard Greenburg, M.D.
M. Allen Pond
Donald Y. Solandt, M.D.
Francis B. Elder, *Secretary*
I.E.S.
Conrad Berens, M.D.
E. C. Crittenden, D.Sc.
E. M. Strong
C. L. Crouch, *Consultant*

Subcommittee on Air Sanitation

Alexander D. Langmuir, M.D., *Chairman,* School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.
Allen D. Brandt, Sc.D.
Hollis S. Ingraham, M.D.
C. G. Loosli, M.D.
James E. Perkins, M.D.
O. H. Robertson, M.D.
Thomas E. Shaffer, M.D.
William F. Wells
H. A. Whittaker
C. P. Yaglou

Subcommittee on Communicable Disease Control

Haven Emerson, M.D., *Chairman,* 156 E. 79th Street, New York, N. Y.
Gaylord W. Anderson, M.D.
J. A. Bell, M.D.
Donald T. Fraser, M.B., D.P.H.
Alexander A. Gilliam, M.D.
John E. Gordon, M.D.
William McD. Hammon, M.D.
James P. Leake, M.D.
Kenneth F. Maxcy, M.D.
Ralph S. Muckenfuss, M.D.
Alton S. Pope, M.D.
Ernest L. Stebbins, M.D.
Franklin H. Top, M.D.
Norman H. Topping, M.D.

Subcommittee on the Hygiene of Housing

C.-E. A. Winslow, Dr.P.H., *Chairman,* 333 Cedar Street, New Haven, Conn.
Frederick J. Adams
Charles S. Ascher
Richard H. Bolt
Rollo H. Britten
F. Stuart Chapin, Ph.D.
Henry S. Churchill
Robert L. Davison
Thomas Fansler
Clarence W. Farrier
Alfred H. Fletcher
L. M. Graves, M.D.
E. R. Krumbiegel, M.D.
Bleecker Marquette
Robert B. Mitchell
Paul Oppermann
M. Allen Pond
F. Carlyle Roberts, Jr.
Mary Rokahr
Abner D. Silverman
Donald Y. Solandt, M.D.
Howard P. Vermilya
H. A. Whittaker
Huntington Williams, M.D.
Coleman Woodbury

Staff: 321 Congress Avenue, New Haven, Conn.
Carl Anderson, *Assistant Field Director*
Eleanor Watkins, *Secretary*

Subcommittee on Research

M. Allen Pond, *Chairman,* U.S.P.H.S., Washington, D. C.

Subcommittee on Standards for Construction and Fundamental Equipment

Henry S. Churchill, *Chairman,* 56 West 45th Street, New York, N. Y.

Subcommittee on Standards for Installed Household Equipment

Mary Rokahr, *Chairman,* U. S. Department of Agriculture, Washington, D. C.

Subcommittee on Standards for Space Design and Occupancy

Abner D. Silverman, *Chairman,* Federal Public Housing Authority, Washington, D. C.

Subcommittee on Substance of Housing Regulations

E. R. Krumbiegel, M.D., *Chairman,* Department of Health, Milwaukee, Wis.

Subcommittee on Morbidity Registration and Statistics

Lowell J. Reed, Ph.D., *Chairman,* The Johns Hopkins University, Baltimore, Md.
Gaylord W. Anderson, M.D.
Edwin L. Crosby, M.D.
W. Thurber Fales, Sc.D.
Ellen W. Jones
James P. Leake, M.D.
Franklin H. Top, M.D.

Subcommittee on Hemolytic Streptococci Research

Franklin H. Top, M.D., *Chairman,* Herman Kiefer Hospital, Detroit, Mich.

Subcommittee for the International List of Causes of Death

Edward S. Rogers, M.D., *Chairman,* School of Public Health, University of California, Berkeley, Calif.

Subcommittee on Sanitation of Food Utensils

Walter D. Tiedeman, *Chairman,* State Department of Health, Albany, N. Y.
A. W. Fuchs, C.E.
N. O. Gunderson, M.D.
Walter L. Mallmann, Ph.D.
Jerome B. Trichter

ASSOCIATION COMMITTEES

Committee on Child Health

Leona Baumgartner, M.D., *Chairman,* City Department of Health, New York, N. Y.
Margaret Adams, R.N.
Allan M. Butler, M.D.
Richard F. Boyd, M.D.
Edwin F. Daily, M.D.
Mayhew Derryberry, Ph.D.
Paul Harper, M.D.
Herbert R. Kobes, M.D.
Frank S. Stafford
Fredrick J. Stare, M.D.
Myron E. Wegman, M.D.

Sedgwick Memorial Medal Committee

Abel Wolman, Dr. Eng., *Chairman,* Johns Hopkins University, Baltimore, M.D.
Reginald M. Atwater, M.D.
Thomas Francis, Jr., M.D.
Wilton L. Halverson, M.D.
William P. Shepard, M.D.
Charles F. Wilinsky, M.D.

SECTION COMMITTEES

Dental Health Section

Committee on Dental Personnel for Local Health Units

J. M. Wisan, D.D.S., *Chairman,* 212 East Superior St., Chicago, Ill.
E. Horace Jones, D.D.S.
Leon R. Kramer, D.D.S.
Frances A. Stoll

Committee on Local Arrangements

David B. Ast, D.D.S., *Chairman,* State Dept. of Health, Albany, N. Y.
Frank C. Cady, D.D.S.
Neil W. Chilton, D.D.S.
Jasper A. Hennigar, D.D.S.
John O. McCall, D.D.S.
Frances A. Stoll

Membership Committee

Olin E. Hoffman, D.D.S., *Chairman,* 1103 Hull Avenue, Des Moines, Iowa
Frank C. Cady, D.D.S.
Donald J. Galagan, D.D.S.
Thomas L. Hagan, D.D.S.
Margaret H. Jeffreys
John W. Knutson, D.D.S.
Leon R. Kramer, D.D.S.
William P. Kroschel, D.D.S.
George A. Nevitt, D.D.S.
Walter J. Pelton, D.D.S.
Carl L. Sebelius, D.D.S.
Frances A. Stoll

Nominating Committee

George A. Nevitt, D.D.S., *Chairman,* U. S. Public Health Service, Richmond, Va.
Margaret H. Jeffreys
William H. Rumbel, D.D.S.

Publications Committee

Thomas W. Clune, D.M.D., *Chairman,* 1282 Cranston Street, Cranston, R. I.
Kenneth A. Easlick, D.D.S.
A. Harry Ostrow, D.D.S.

Resolutions Committee

R. C. Leonard, D.D.S., *Chairman,* State Department of Health, Baltimore, Md.
Lyman D. Heacock, D.D.S.
William H. Rumbel, D.D.S.

Committee To Study Feasibility of Public Health Dental Specialty Boards

Kenneth A. Easlick, D.D.S., *Chairman,* University of Michigan, Ann Arbor, Mich.
Linwood G. Grace, D.D.S.
Allen O. Gruebbel, D.D.S.
John W. Knutson, D.D.S.
Hugo M. Kulstad, D.D.S.

Engineering Section

Committee on Air Pollution

H. A. Whittaker, *Chairman,* University of Minnesota School of Public Health, Minneapolis, Minn.
John Buxell
Gordon M. Fair
Burgess H. Jennings
Sol Pincus, C.E.

Advisers:

Epidemiology Section
Hollis S. Ingraham, M.D.

Industrial Hygiene Section
C. P. Yaglou

Laboratory Section
Stuart Mudd, M.D.

Committee on Bathing Places (Joint with the Conference of State Sanitary Engineers)

Warren J. Scott, *Chairman,* State Department of Health, Hartford, Conn.
Alfred H. Fletcher
Thomas M. Riddick
Louis F. Warrick

Advisers:

Epidemiology Section
Ralph E. Wheeler, M.D.

Laboratory Section
Walter L. Mallmann, Ph.D.

Committee on Exploration of Research Needs

Francis B. Elder, *Chairman,* 1790 Broadway, New York, N. Y.
Emil T. Chanlett
V. M. Ehlers
Harold B. Gotaas
Sol Pincus, C.E.
Blucher A. Poole

Adviser:

Industrial Hygiene Section

Richard T. Page

Committee on Membership and Fellowship

H. E. Miller, *Chairman,* University of Michigan, Ann Arbor, Mich.
Morris M. Cohn, C.E.
Morton S. Hilbert
Harold Stephens Hutton, C.E.
Benn J. Leland
Walter S. Mangold
John B. Miller
James L. Rowland, Jr.
Earle W. Sudderth
Louis F. Warrick
Arthur D. Weston

Committee on Milk Sanitation

Harold S. Adams, *Chairman,* State Department of Health, St. Paul, Minn.
Harold J. Barnum
Edwin Ludewig
Samuel I. Reed
Alexander A. Robertson
H. L. Thomasson
Harold Wainess

Committee on Municipal Public Health Engineering

Morton S. Hilbert, *Chairman,* 611 N. Waverly Drive, Dearborn, Mich.
Joel C. Beall
William H. Cary, Jr., C.E.
William J. Dixon
Herbert J. Dunsmore
William R. Hardy
A. H. Herberger
Henry D. Peters
Charles L. Senn

Committee on Rural Sanitation

William T. Ingram, *Chairman,* 1790 Broadway, New York, N. Y.
Paul D. Haney
Albert I. Howd
H. A. Kroeze
David B. Lee
Kenneth H. Spies
Earle W. Sudderth
Jerome H. Svore
Samuel R. Weibel

Committee on School Sanitation

Herbert J. Dunsmore, *Chairman,* City Health Dept., Pittsburgh, Pa.
Leonard M. Board
Richard G. Bond
L. M. Clarkson
Albert W. Happy, Jr.
Samuel P. Kingston
Edwin L. Ruppert

Advisers:

School Health Section

Warren H. Southworth, Dr.P.H.

Public Health Education Section

Clair E. Turner, Dr.P.H.

Committee on Sewage Disposal

Louis F. Warrick, *Chairman,* State Health Department, Madison, Wis.
F. E. DeMartini
Ralph E. Fuhrman
William Q. Kehr
Theodore J. Lafreniere
E. A. Reinke
Willem Rudolfs, Ph.D.
C. J. Velz

Committee on Shellfish

Edward Wright, *Chairman,* State Department of Public Health, Boston, Mass.
Milton H. Bidwell
L. M. Fisher, C.E.
Joseph B. Glancy
R. S. Green
Clarence W. Klassen
Joseph J. Maguire
Richard Messer
Thurlow C. Nelson, D.Sc.
Kenneth H. Spies

Adviser:

Laboratory Section

To be appointed

Committee on Training

Ellis S. Tisdale, *Chairman,* Communicable Disease Center, U.S.P.H.S., Atlanta, Ga.
Harold S. Adams
Leon A. Bradley, Ph.D.
Gilbert H. Dunstan
William C. Gibson
H. E. Miller
Thorndyke Saville

Subcommittee on Undergraduate Academic Education

John M. Hepler, C.E., *Chairman,* State Dept. of Health, Lansing, Mich.
Leon A. Bradley, Ph.D.
Herbert J. Dunsmore
Samuel H. Hopper, Ph.D.
Walter S. Mangold

Subcommittee on Graduate Academic Education

Clarence W. Klassen, *Chairman,* State Dept. of Health, Springfield, Ill.

Herman G. Baity, Sc.D.
Gilbert H. Dunstan
Harold B. Gotaas, Sc.D.
John M. Henderson
Harold A. Whittaker

Subcommittee on Field Training

William C. Gibson, *Chairman,* University of North Carolina School of Public Health, Chapel Hill, N. C.
Harold S. Adams
H. E. Eagan
Charles L. Senn
Charles D. Spangler, C.E.

Committee on Water Supply

Charles R. Cox, *Chairman,* State Department of Health, Albany, N. Y.
H. J. Darcey
Ray L. Derby
Raymond J. Faust
Arthur E. Gorman
Harold S. Hutton
Major Raymond J. Karpen, M.S.C.
Arthur D. Weston

Policy Advisory Committee to the Section Council

Joel C. Beall, *Chairman,* Macon-Bibb County Health Dept., Macon, Ga.
E. L. Baldwin
W. P. Boylston
William H. Cary, Jr., C.E.
Charles R. Cox
Gordon M. Fair
Morton S. Hilbert
William T. Ingram
Ferdinand A. Korff
David B. Lee
Harry E. Miller
Mitchell P. Mondala
Louis W. Pickles, C.E.
Harold B. Robinson

Epidemiology Section

Committee on Bathing Places (to coöperate with the Committee on Bathing Places of the Engineering Section)

Ralph E. Wheeler, M.D., *Adviser*

Committee on Air Pollution (to coöperate with the Committee on Air Pollution of the Engineering Section)

Hollis E. Ingraham, M.D., *Adviser*

Food and Nutrition Section

Committee on Chemicals Introduced in Foods

Franklin C. Bing, Ph.D., *Chairman,* American Institute of Baking, Chicago, Ill.
(Personnel to be appointed)

Committee on Membership and Fellowship

Marjorie M. Heseltine, *Chairman,* U. S. Children's Bureau, Washington, D. C.
Enos B. Buchanan
Edna Mae McIntosh
Frederic W. Nordsiek
Harold R. Sandstead, M.D.
Frances N. Shoun

Nominating Committee

Ethel Austin Martin, *Chairman,* National Dairy Council, Chicago, Ill.
Marietta Eichelberger, Ph.D.
Bernard E. Proctor, Ph.D.
Glenn G. Slocum, Ph.D.

Committee on Sanitary Practices in the Food Industry

Harry E. Goresline, Ph.D., *Chairman,* U. S. Department of Agriculture, Washington, D. C.
Paul S. Prickett, Ph.D., *Vice-Chairman*
Harold S. Adams
J. Lloyd Barron, C.E.
Gail M. Dack, M.D.
V. L. Ellicott, M.D.
Edward L. Holmes, Ph.D.
Lloyd B. Jensen, Ph.D.
Cyril K. Johns, Ph.D.
Walter L. Mallmann, Ph.D.
Joseph G. Molner, M.D.
E. H. Parfitt, Ph.D.
Glenn G. Slocum, Ph.D.

Health Officers Section

Committee on Professional Education

V. A. Van Volkenburgh, M.D., *Chairman,* State Department of Health, Albany, N. Y.
C. F. Blankenship, M.D.
John Hackler, M.D.
E. A. Piszczek, M.D.

Committee on Salary Schedules

Edward G. McGavran, M.D., *Chairman,* University of North Carolina, Chapel Hill, N. C.

Report of the Chairman of the Executive Board of the American Public Health Association to the Governing Council, 1947-1948

AS the Association marked in 1947 the 75th anniversary of its founding, the Chairman of the Executive Board called the attention of the Governing Council to the growing pains that had been experienced in the organization during the preceding year. The Association with its dynamic program had outgrown its headquarters, staff, and its previously defined boundaries, and the Executive Board, it will be recalled, with the staff had given extended time to the solution of the attendant problems. These involved changes in the Constitution and By-Laws, a complete appraisal and renovation of the mechanics of the Annual Meeting, rearrangement with reference to editorial responsibilities of the *Journal,* the establishment of a new Association-wide Coördinating Committee on Laboratory Methods, and many other growing changes.

The year now ending has again reflected the growth of a dynamic organization in touch with the times and changing its structure from time to time to meet the changing conditions. This is a wholesome process.

INCOME FROM MEMBERSHIP AND SPECIAL FUNDS

At the 1947 Annual Meeting the Governing Council voted to increase Association dues from $5 to $7 for members and from $10 to $12 for Fellows. Life Membership dues were increased from $100 to $200. This was the first change in membership dues in 75 years. The Council will wish to know the result of this decision on the membership income of the Association.

The renewal rate for 1948 has stood very close to that for 1947, the figures as of September 1 being 91.3 per cent for 1948 and 93.3 per cent for 1947. The 1948 applications for Fellowship stand at a high level, namely 261 as compared with 142 for 1947. Life Membership applications were received at the old rate up to December 31, 1947, and the Council will act this year on 164 applications, an all-time high. In the 12 months since the last Report to the Council (as of September 1) there were 1,227 applications for membership in the Association. This compares with a 5 year average in the preceding period of 1,377. The total membership as of September 1, 1948, stood at 11,531.

The Executive Board regards this record as very gratifying and it believes that the Governing Council was well advised to take the steps in 1947 which revised the financial structure in this way. Membership income, including that from members, Fellows, Affiliated Societies, Branches, and Sustaining Members, is expected to reach $82,160 in 1948, an increase of $15,460 over the actual income for 1947. Most of this difference goes back to the change in dues.

MEMBERSHIP INCOME AND THE ASSOCIATION BUDGET

The Chairman of the Executive Board believes that the Governing Council

members should understand the fundamental nature of this membership income in the Association budget. It represents the only large amount of unallocated funds at the disposal of the Executive Board. It is possible to provide from this source those funds necessary to publish and distribute the *American Journal of Public Health,* to operate the Annual Meeting, and to maintain the most essential parts of the committee structure through which professional goals are progressively achieved. These may be described as the basic functions of any professional society.

It is evident to anyone familiar with the A.P.H.A. that there are many activities carried out over the years above and beyond this limited service. To a very large extent the activities of the Committee on Administrative Practice during the last 28 years have been financed by grants and other income outside this nucleus at the disposal of the Association. During this period funds of at least $800,000 have been contributed by foundations, life insurance companies, and governments to make possible the work of this one Standing Committee of the Association. As a result field consultation services have been available, often at no cost or at a fraction of the actual cost, to states and municipalities wishing to use them. Surveys have been made, evaluation methods have been developed, and summaries have been published (as in *Health Practice Indices)* that have been distinctly useful.

Likewise the Committee on Professional Education has operated services financed by grants which have supplemented the activities of this Standing Committee in several respects. Since 1941 the Merit System Service has constructed examinations for the selection of public health personnel. These have been used by 35 states and some smaller areas and by the U. S. Public Health Service for the selection of its own appointees. Funds aggregating more than $150,000 have been made available for this purpose. Another separately financed project of the C. P. E. relates to the accreditation of schools of public health. During the last 3 years the Commonwealth Fund has made available for this purpose a sum of $27,000.

In each of these instances as well as in the case of the Committee on the Hygiene of Housing, these outside funds have been utilized to advance the purposes for which they were given, but none of these funds have been used for the upkeep of the services underlying the special objective. Without a considerable staff and organization financed by the Association itself, these notable projects could not have been operated. With such a basic organization and staff, these and others can be operated for the benefit of the public and for the advancement of the professions making up today's public health.

To put it in another way, it should be noted that membership dues of the Association even at the increased rate will account for only 20 per cent of the Association's income in 1948. For every dollar paid in membership dues $6.50 must come from other sources to carry on the work of the Sections. of the Committee on Administrative Practice, the Committee on Professional Education, the Merit System Service, the Vocational Counseling and Placement Service, the Information Service, the Subcommittee on the Hygiene of Housing, the Subcommittee on Medical Care, the Engineering Section Project, and numerous other committee and Association activities.

A SOUND BUDGET PERMITS EXPANSION

It is the considered opinion of the Executive Board that the Association now stands in a much sounder position with the increased membership income and that this pattern of encouraging out-

side projects can be further extended. In addition the membership and Fellowship have received dividends on their dues during 1948 which have been appreciated. Among these are the Supplement to the January issue of the *Journal* containing the addresses from the extraordinary Special Sessions held at the Atlantic City meeting. Another dividend is the *Year Book* which carried a wealth of Association information and which was distributed free with the May *Journal*. Still another benefit lies in the enlarged *Journal* which in the first 8 months of 1948 contained 1,200 text pages as compared with 1,088 text pages in the corresponding period of 1947.

The Executive Board believes that a prior claim on any remaining funds from this increase of dues should be an extension of the professional staff in the central office. It was 14 years ago that the Board as a matter of faith set itself to support a full-time, professionally trained physician as Executive Secretary. Other staff members have been added from time to time so that at present the professional members of the staff on full time include 5 physicians, 2 engineers, 2 housing experts, statistically trained persons, and an excellent supporting staff. Several part-time individuals serve the Association and the *Journal* in various capacities. The Board is now of the opinion that the time has come to add another medically trained public health administrator to the central staff and it has sought for some months to find the right associate for the Executive Secretary. Such a person will make it possible for the public relations activities of the Association to be developed more adequately. The Board appreciates the excellent progress that has been achieved to date even without a staff fully adequate in numbers. It will readily be seen that there is no difficulty in alloting these new funds for useful purposes.

RELATIONS WITH THE NATIONAL HEALTH COUNCIL

The Governing Council will recall that the Association has been an active member of the National Health Council since the creation of that agency in 1921. This has provided opportunity for the Association to be well housed in convenient relationship to many other national (or international) agencies and has made possible the development of the National Health Library and similar services which would have been beyond the reach of single agencies.

The Association took a leading part in stimulating a four year study of national health agencies which was concluded in 1945 under a grant from the Rockefeller Foundation. Since that time plans for expanding the National Health Council have been laid with the aim that it might become a useful agency for joint planning among national health interests. This plan has been effectuated in 1948 with the appointment of a full-time and well qualified executive director for the Council and through the support of national health agencies and the Rockefeller Foundation. During the last 2 years the Executive Secretary of the Association has served in a voluntary capacity as Secretary of the National Health Council and a considerable load of organization has fallen on him during the developmental period. Several other members of the Governing Council and of the Executive Board have served in close coöperation during these years. We believe that the future of the National Health Council has great promise and that some of the goals of the Association can best be secured through these channels. A first rate example of this fact lies in the help which the National Health Council has already provided in the planning for local health units to cover the nation. Other A.P.H.A. goals such as the cultivation of strong citizen support for public health can be advanced likewise

through the National Health Council.

REVISIONS PROPOSED FOR CONSTITUTION AND BY-LAWS

The Governing Council has on several recent occasions expressed appreciation for the service rendered by the Committee on Constitution and By-laws. Periodic revisions of these documents appear to have kept them abreast of the Association's growth. It is the opinion of the Executive Board that the report which will be presented this year by this Committee is again important and worthy of close study. Members of the Council have already been advised of the proposed revision of the Constitution for the purpose of broadening the participation of members in the voting. The Board believes that this is a wise step and that the impression now abroad among members that they should have greater voting power is well founded. There is no proposal to change the provision that the officers of the Association, members of the Governing Council and Committee Chairmen must be Fellows. It is proposed, however, to allow both Fellows and members to vote for Elective Councillors and by mail, so that attendance at the Annual Meeting will not be required for exercise of the franchise. The Board urges the members of the Governing Council to use their influence in supporting this proposal which will be voted on by the Fellows present at the Boston meeting in November. Suitable new By-Laws will be presented to the Council in Boston to implement the Constitutional changes if they are approved.

NEW ASSOCIATION ACTIVITIES

At the 75th Annual Meeting consideration was given to the appointment of a special Association Committee on Child Health with representation from the Maternal and Child Health, School Health, Health Officers, Public Health Nursing, and Public Health Education Sections. The Executive Board has established this Committee under the Chairmanship of Dr. Leona Baumgartner and a thorough effort has been made to finance activities that relate to the health and medical care of children and to maternity care. It is also expected that this Committee will act for the A.P.H.A. in its relations with national organizations and agencies, professional and non-professional, which are concerned with the advancement of child health. Activities along these lines are well underway, especially with reference to the American Academy of Pediatrics and its Committee on Improvement of Child Health. It is expected that the program of this Committee on Child Health will include the development of recommended standards, procedures and policies, studies of content of program, standards of performance, recommendations regarding undergraduate and graduate education of professional and technical workers in this field and the research or investigations required.

The Committee on Research and Standards has reactivated its Subcommittee on Communicable Disease Control looking toward a new edition of the *Control of Communicable Diseases* in 1950. For more than 30 years the Association has prepared and published this comprehensive report that has world-wide acceptance. The 1945 edition was prepared with the coöperation of the British Ministry of Health as well as with American official agencies. It is anticipated that the 1950 edition will include participation of the appropriate North American agencies, including Canada, and that in addition the British and Scottish Ministries of Health will be represented. In all probability, coöperation will be arranged with the World Health Organization in order that to an increasing extent this report may become an international document. In the meantime, the Association is proud to have had sponsored this ac-

tivity over more than 3 decades, all of which has been under the Chairmanship of Dr. Haven Emerson.

STANDING COMMITTEE REPORTS

Again this year we shall hear reports from Dr. William P. Shepard, Chairman of the Committee on Professional Education; Dr. Wilton L. Halverson, Chairman of the Committee on Administrative Practice; and Dr. Thomas Francis, Jr., Chairman of the Committee on Research and Standards. Inasmuch as these reports will be presented at the Boston meeting and published in the *Year Book,* I need not systematically review their content, but in the case of each of these Standing Committees, good progress has been achieved during the year. The Governing Council will wish me, on behalf of the Association at large, to express cordial appreciation of the faithful service of these Committee Chairmen and of the members of these Committees around whom the professional work of the Association is organized.

Another important Standing Committee which functions most actively at the time of the Annual Meeting is the Committee on Eligibility under the Chairmanship of Dr. Vlado A. Getting, whose Committee has reviewed at the request of the Executive Board the practice of other professional societies in the remission of dues to members of long standing. A proposal will be brought before the Governing Council at the Boston meeting having the approval of the Executive Board and the Committee on Constitution and By-Laws which seeks to set up a modest but effective way of relieving our colleagues of membership dues at the time of retirement after membership of at least 30 years' duration.

MEMBERSHIP

On September 1, 1948, the total membership was 11,531 as compared with the figure in the preceding year at the same time of 11,382. Since the Association last met in Boston in 1923 there has been a net increase of 8,588 in the membership. Ten years ago the membership was less than half the present figure.

Of our more than 11,000 members, *1,874* are Fellows. Two hundred sixty-one applications for Fellowship will be considered by the Committee on Eligibility at the Boston meeting.

The circulation of the *American Journal of Public Health* has continued high during the year and now reaches *13,945* members and subscribers each month. The adjustment of advertising rates made in 1947 seems to have been equitable and wise.

SOME SPECIAL DIFFICULTIES

The Governing Council should know that it has become increasingly difficult to finance two of the activities of the Association which have already made lasting contributions. I refer to the program of the Subcommittee on the Hygiene of Housing first established in 1937 and conducted since then under the leadership of Professor Winslow and with an effective staff. The members of the Council will recall the publication *Basic Principles of Healthful Housing* which has had a decade of usefulness, and more recently the *Appraisal Method for Measuring the Quality of Housing,* now available in four volumes, providing the first objective means of measuring the sanitary quality of housing available to health departments, city planners, and housing authorities. This activity grew out of the work of the Health Committee of the League of Nations years ago and compares favorably with the other national committees on housing set up at that time of which this is believed to have been the only one under nonofficial auspices. Well over $100,000 has been expended in the promotion of this task and Professor

Winslow and the members of the Committee are to be highly commended. The value of these services is not to be measured in dollars but it is to be hoped that the dollars necessary to carry it on can be found from among those persons and agencies with foresight who see the significant value in this work.

In this connection it is a pleasure to record the sustained support which has been received from the Milbank Memorial Fund across the years in this project. Other agencies contributing have included the National Tuberculosis Association, the Woman's Foundation, the Metropolitan Life Insurance Company, and other groups whose support is greatly appreciated.

The other present activity of the Association whose support is threatened is the Engineering Section Project described a year ago which looked forward to research and demonstration in the field of administrative practice as applied to environmental sanitation, including such basic factors as job evaluation and program evaluation. The whole field of training and education for personnel to be employed in this specialty has been given systematic review. The first two years of the project have been concluded under the joint support of the National Foundation for Infantile Paralysis and a group of firms related to community sanitation. Their combined support has made possible the employment of an engineering field associate whose work is suitably coördinated with the Engineering Section, the Committee on Administrative Practice, and the Committee on Professional Education. Again it is hoped that the merit of this project will be apparent to those who can see its inherent values.

ACKNOWLEDGMENTS

The Executive Board is happy to acknowledge the indebtedness of the Association and of the public health professions to the officers, the Governing Council members, the Sections, and the numerous Association and Section Committees which have functioned with enthusiasm and effectiveness during the past year.

Again we extend our appreciation and gratitude for the financial support which comes from many sources. We recognize that the work of the Committee on Administrative Practice again has been dependent on the generous and continuing support of the Commonwealth Fund given for the program of the Subcommittee on State and Local Health Administration. A three year program for the Accreditation of Schools of Public Health as originally set up has now been completed as a joint project between the Association and the Commonwealth Fund, the latter supplying the operating support.

Again the work of the Subcommittee on Local Health Units which has been linked in 1948 with the new program of the National Health Council has been made possible by the W. K. Kellogg Foundation. The activities of the Subcommittee on Medical Care have again been supported by a generous grant from the Rockefeller Foundation. The American Drug Manufacturers Association has continued its support of the studies on pertussis antigen made under the auspices of the Subcommittee on Evaluation of Administrative Practice.

The Merit System Service and Vocational Counseling and Placement Service through part of the year have been maintained in partnership with the U. S. Public Health Service, the Children's Bureau, and the National Foundation for Infantile Paralysis.

The Albert and Mary Lasker Foundation provides the Lasker Awards and funds for their administration.

Special mention is due to the faithful support received from our Sustaining Members which in the aggregate amounted to $8,000 in the general budget. Without this unrestricted

money some of the most fruitful services of Association committees would have been impossible as, for example, the publication in 1948 of the 9th edition of *Standard Methods for the Examination of Dairy Products*.

Of course there should be mentioned the enduring loyalty of thousands of those from whom this professional society calls out the best in voluntary service. It is a priceless ingredient to find busy doctors, engineers, and nurses, to mention only three groups, eager and ready to assume new tasks for the common good. The Association needs their help.

Again it is a pleasure to acknowledge the loyalty and intelligence of the permanent staff who make these accomplishments possible.

Once again, the Board has satisfaction in reporting another useful year to the Governing Council.

ABEL WOLMAN, DR.ENG., *Chairman*

Administrative Practice*

SIGNIFICANT public health developments in the Northeastern area of the United States are of particular interest to the committee. A more liberal administrative attitude toward the consolidation of units of government for effective local health services is noted. A state study became a public record in the Commonwealth of Massachusetts, the evaluation process has been adopted as a basis for program planning and linked with the grant-in-aid administration in New York State, and a year-long study in Pennsylvania is being completed.

In many other states the extent of citizen interest in both expanding and improving community health services would indicate a more liberal administrative attitude elsewhere. As an illustration of the kind of ferment that is going on, the committee has received requests for *Health Practice Indices* from the health chairmen of 53 business and professional women's clubs in 26 states, following its mention as a useful tool in the club women's national magazine *Independent Woman*. These requests were fully answered and referred to the state health department, as well. This is an interesting illustration of the use of information service and the *Indices* as an introduction to education about the broader aspects of community health development.

Local Health Units, Haven Emerson, M.D., Chairman

During the current year the soil prepared through the Princeton Conference for local health units has been continuously cultivated by the National Advisory Committee on Local Health Units of the National Health Council. The Council is meshing its program for encouraging the development of local health councils with that of extending health services through local initiative and support. The subcommittee is an integral part of this program in several ways: its chairman serves as the Association representative on this committee; a grant to the Association from the W. K. Kellogg Foundation has enabled it to share in large measure in the financial support of the program; the committee's research assistant serves as the secretary of the National Advisory Committee.

Important events of the year have been the two regional conferences, each covering five states, held in Indiana in April and in Salt Lake City in October. With teams of professional and lay persons interested in community health service, selected by the state health officers, these have served to clarify both the general problems and the specific ones of the separate states, and have given tremendous support to the local health unit program. It is perhaps worth noting that a general citizen understanding of the significance of local health services has no little influence on recruiting young persons to enter the public health field.

The extent to which many of the Princeton agencies have identified themselves with this program has more than justified the Princeton Conference. The National Grange, American Social Hygiene Association, National Society for Prevention of Blindness, National Organization for Public Health Nursing, National Society for Crippled Children and Adults, and the National Tuberculosis Association have each passed reso-

* Report of the Chairman of the Committee to the Governing Council, November 8, 1948.

lutions carrying out the intent of the Princeton resolutions. The National Congress of Parents and Teachers sponsored the National Health Services Act of 1948, and will work for it in the 81st Congress. Both the Lions International and the National Tuberculosis Association devoted a half day of their recent annual meetings to local health units.

Medical Care, Joseph W. Mountin, M.D., Chairman

The statement on "Coördination of Hospitals and Health Departments," prepared by a joint committee with the American Hospital Association, was approved by both associations and published in the May, 1948, issue of the *American Journal of Public Health.* The American Hospital Association has distributed reprints of this official statement of policy to all of its member institutions.

The Joint Committee on Chronic Disease of the American Hospital Association, American Medical Association, American Public Health Association, and American Public Welfare Association is now discussing plans for the establishment of a broadly representative national commission to make a comprehensive study of chronic illness.

The Maryland Medical Care Program, a study by the staff of the Subcommittee on Medical Care, was published in March, 1948, and distributed to more than 2,500 individuals, including state and local health department personnel, officials of state medical societies, and members of the public welfare profession.

The staff is currently engaged in a field study of general medical care programs administered by local health departments, with a view to publishing a compendium describing the main features of these programs. Also in progress is a field investigation of coördinated activities of local health departments and hospitals which are jointly housed.

A report on *Regionalization in New England,* has been widely circulated. This report gives a detailed account of the activities of the Bingham Associates Fund in promoting closer coördination of medical services on a regional basis.

Study groups are in process of formulating specific recommendations on: (1) The role of voluntary plans in a national medical care program; (2) Intergovernmental relationships in a national medical care program, in collaboration with the Subcommittee on State and Local Health Administration of the C.A.P.; (3) Methods of improving the quality of medical care; (4) The regionalization of hospital and other medical services; (5) The use of auxiliary personnel in dental care programs; and (6) The development of programs for the control of specific chronic diseases.

The subcommittee has continued to prepare medical care bibliographies for the use of health officers and other public health personnel. Additions to this series have included bibliographies on regionalization of medical services and on group medical practice.

The subcommittee has arranged for two sessions at the 76th Annual Meeting of the Association on "Improving the Quality of Medical Care" and "Medical Care Programs: Problems and Methods." It has also collaborated in the development of joint sessions with the Public Health Nursing, Industrial Hygiene, Dental Health, and Engineering Sections.

Evaluation of Administrative Practices, Haven Emerson, M.D., Chairman

The pertussis studies have been carried forward with the continued financial support of manufacturers of biologic products. The work has included experiments in which various cultures of *H. pertussis* and a few para-pertussis and bronchiseptica strains are compared with respect to their virulence and immunizing properties in mice. In addi-

tion, during the year more than 30 protection tests were carried out with sera and the necessary work done related to testing and maintaining a large stock of cultures.

The Study Group on Tuberculosis Control Procedures is collaborating with other authorities regarding a revision of the *Manual on Tuberculosis Case Finding,* previously published by the A.P.H.A. and the National Tuberculosis Association. The Study Group is also concerned with the place of BCG vaccination in a tuberculosis control program. This subject has been under careful study by the Division of Tuberculosis of the U.S.P.H.S. and a representative advisory group who have indicated that the use of BCG should be subjected to further experimental studies. The Study Group will give this matter further consideration as to recommendations that may be available to health officers who are interested.

The report of a five years' study on the use of multiple antigens is expected to be ready for publication before the end of the year.

Unfortunately, a revised Iodized Salt Bill, prepared by the Study Group on Endemic Goiter and sponsored by Congresswoman Frances P. Bolton, was rejected in Congressional Committee. The attention of the Study Group is now focused on state regulation of this measure.

Study and analysis of carrier control procedures in the various states has recently been completed by the Study Committee on Typhoid Fever. Recommended methods for discovery, examination, and control, as well as criteria for the cure of typhoid carriers will be included in the committee's report.

The Study Committee on Hemolytic Streptococcal Infections (which is the new name of the original Study Group on Scarlet Fever) held a two day conference on November 6 and 7 with a number of invited consultants in this field. The group reviewed the sections on rheumatic fever and acute hemolytic streptococcal infections in the Association's report *The Control of Communicable Diseases,* and submitted proposed changes to the Subcommittee on Communicable Disease Control of the Committee on Research and Standards, in charge of the revision of this report.

State and Local Health Administration, Ira V. Hiscock, Chairman

A re-study was made in California early this year at the request of the state. It is significant to observe that this rapidly growing, vigorous health department has made extensive use of the previous study and has adopted a large majority of the recommendations. It is interesting, too, to recognize that the study techniques can be reapplied with profit on a somewhat different level, that is, with regard to the finer details of administrative practice.

The major states of Massachusetts and Pennsylvania have been studied since last October. These studies are of unusual importance not only because of the size and complexity of the administrative problems but because of their general application to the heavily populated northeastern section of the United States. A practical method for the establishment of local health units in Massachusetts which would have the support of legislators and local health officers is being developed through a notable state committee.

The study in Pennsylvania has furnished unusual opportunity to explore new patterns of state studies. The Commonwealth of Pennsylvania provided $35,000 from federal funds toward the support of the study. This made it possible to secure qualified consultants in such fields as fiscal administration, personnel management, tuberculosis sanatorium administration, rheumatic fever control, and also to secure the benefits of group thinking of other agencies and

personnel, in local and state government, rural sociology, volunteer nursing, legislation, etc. The technique of institute group discussion was used, giving the participants opportunity to assist in the development of recommendations. At least one thousand copies of the report will be printed.

A short follow-up visit with a rapid review of a previous state study was made in Oklahoma. It was interesting to note that the majority of the recommendations of the 1938 study had been carried out. Many of the policies and the methods of operation clearly follow the survey. Visits were made by the Field Director to the states of Ohio and West Virginia for the specific purpose of discussing survey technique, of meeting with substantial groups of citizens to discuss basic needs of the health department, and to consult with the State Health Officer regarding changing policy of local health administration.

A significant local study was made in Kansas City, Mo., through coöperation of the field staff. This suvey, officially in charge of Community Surveys, Inc., was an attempt to study community organization as a whole in the fields of dependency, child care, health, recreation, culture, and adult education, particularly with regard to trust fund administration. The committee appreciates the opportunity to collaborate with Community Surveys, Inc., and believes that studies of this type are helpful in that they include all the related social sciences.

The Evaluation Project has made genuine progress. The efforts of this Project (now in its 28th year) to establish practical tools, to develop a better understanding of methods, and more firmly establish evaluation as an integral part of public health, are increasingly recognized in meetings with related groups, in published articles, and statements by competent public health authorities. Specific instances of the use of the *Schedule* in schools of public health and in field consultant services are a notable gain.

There appears to be a growing interest on the part of state health departments to accept responsibility for the use of the *Schedule* as a part of their normal evaluation process. Michigan graded schedules completed by 32 of its local units. As a by-product of the 61 schedules submitted from New York State, special statistical studies will be conducted which may present new factual evidence concerning the contrast of areas with and without organized public health services.

The *Evaluation Schedule* was expanded by the completion and release of the *Sanitation Evaluation Schedule* for use in the study and appraisal of community sanitation programs. Copies of the *Schedule* and a *Guide* to its use have been sent to all state health departments, and many city departments, to interested representatives of other fields of engineering and to schools of public health. In the opinion of the staff, the *Sanitation Schedule* represents an advance in the evaluation technique, particularly in the fact that the three basic areas—facilities, effort, and status —are more clearly defined than has been possible heretofore. Unfortunately funds are in sight only until the end of 1948 to provide field service by a qualified engineer in the development of this *Schedule*.

Additional expansion of the overall schedule by the preparation of a special schedule on Dental Health is now under way. Authorities in the field of mental health are interested in the development of a schedule on Mental Health. While these specialized schedules are to be used for experimental purposes, it is hoped that after sufficient field trial, certain items will be incorporated in the next revision of the overall schedule.

Accident Prevention, Donald B. Armstrong, M.D., Chairman

Representatives of the Subcommittee on Accident Prevention have continued active coöperation with the National Safety Council and other agencies in this field. They have been particularly active in the reorganization of the National Home Safety Conference.

In the programs on home safety at the annual meetings of the National Safety Council and the American Public Health Association, attention is given to the newer approaches to accident control, including their public health and epidemiological aspects, together with the emotional elements in accident proneness, and the motivative psychological factors in education for accident prevention.

The section on Accident Prevention in the revised *Evaluation Schedule* was featured in the Health Education Exhibit of the National Publicity Council at the Association Annual Meeting.

Public Health Nursing, Marie L. Johnson, R.N.

A statement on "Public Health and Bedside Home Nursing Services," approved by the Committee on Administrative Practice, was published in the January, 1948, *American Journal of Public Health*. This is an amplification of the statement prepared by the Committee on Nursing Administration in coöperation with a group of national and federal agencies interested in public health nursing. An outgrowth of the work of this group has been the organization of a committee of public health consultants representative of national and federal agencies to discuss and clarify common problems and to formulate and promote basic principles of organization and service.

It seems increasingly clear from the deliberations of various committees that there must be found suitable methods of integrating all public health nursing services in a community whether they be financed by funds from contributions or from taxes, as well as to find suitable administrative methods for pooling such funds.

A statement, entitled "Urgent Message to Employers of Public Health Nurses," which includes a suggested salary scale for field nurses, has been distributed to health officers, governors, mayors, chest executives, and others, by the National Organization for Public Health Nursing.

A study of costs in public health nursing has been under way since December, 1946. On the basis of material collected, a cost manual has been prepared and is now being tested in different types of agencies.

Staff Changes

Dr. Roscoe P. Kandle accepted appointment as Field Director on February 1, 1948, when the Association lost Dr. Carl E. Buck to the University of Michigan.

Summary

In summary, the committee on Administrative Practice can report two state studies, one resurvey, increasing active use of the *Evaluation Schedule* in ever-broadening and rather remarkable different ways, research to determine its validity, a new *Schedule* on Environmental Sanitation which it appears will get into use quickly without the long promotional period that was necessary with the parent *Schedule*, the Dental Schedule on the way, the nation-wide surge of action of voluntary agencies in the development of local health services now linked with the youthful and exuberant efforts of the National Health Council, real progress in administrative control problems of Hemolytic Streptococcal Infections, additional significant knowledge in pertussis immunizing agents. These are but a few of the efforts in many fields in which this committee is active and plans to carry

on its program for the coming year.

The committee would be remiss not to acknowledge the financial and moral support given to its work by The Commonwealth Fund, The Rockefeller Foundation, The W. K. Kellogg Foundation. the U. S. Public Health Service, and drug manufacturers.

WILTON L. HALVERSON, M.D.,
Chairman

Eligibility*

THE Committee on Eligibility recommends for election to Fellowship in the American Public Health Association the largest number of members to request this status since Fellowship was established in 1922. A total of 259 Fellowship applications were received this year, of which 252 passed the twelve Section Councils and the Executive Board (acting on unaffiliated applications), and 250 have been approved by the committee. The names of the applicants recommended for Fellowship by the Committee on Eligibility appear on the lists that have been distributed to members of the Governing Council.

This large number of applications is due in part to a statement appearing in several 1948 issues of the *American Journal of Public Health* setting forth in detail the requirements and privileges of Fellowship. Many members were under the impression that they must wait for an invitation before applying, and, although the published statement resulted in the submission of a few applications from persons who are not professionally qualified, on the whole the current list of applicants contains excellent candidates in the various branches of the profession. It is a wholesome indication of a desire to be of recognized professional standing.

It should be remembered that the By-laws state that "persons who have been members for at least two years and are of established professional standing shall be eligible for election as Fellows." Therefore any member who has been affiliated for at least two years who wishes to apply for Fellowship must be permitted to do so. The Section Councils and the Committee on Eligibility are the groups within the Association that must carefully examine the credentials of persons requesting Fellowship, and theirs is the very important responsibility of denying admittance to unqualified persons before the names are submitted to the Governing Council for final action. This year the Section Councils were warned to be particularly careful in screening the applicants in their Sections. The Eligibility Committee, in considering the applications that passed the Section Councils, measured each one against the six paragraphs in the By-laws defining persons of established professional standing, spending most of the day on this arduous task.

This large number of new Fellows will increase the total Fellowship to slightly over 2,100, or just under 19 per cent of the total membership. It is rather striking how closely the percentage of Fellows has remained at this level as the Association has grown.

The number of applicants for membership in the year ending August 30, 1948, that the committee approved for membership in the Association was 1,227. This is a few hundred less than the number requesting affiliation during the 1946–1947 period. It reflects to some extent the rise in membership dues and the low compensation levels of public health workers.

The Chairman of the Executive Board has already reported to the Governing Council the membership situation in this first year of increased dues, but since the Committee on Eligibility has been interested in the reception that the dues increase received, being one of the groups which recommended that an increase be made, I wish to express for the members of my committee our pleasure in learning that the Associa-

* Report of the Chairman to the Governing Council, November 8, 1948.

tion's membership income as of August 31, 1948, is $15,000 higher than on the same date in 1947, as a result of the extra dues received from members and Fellows this year. This added income has enabled the Association to enlarge the *Journal*, to publish a *Year Book* once more, and to bring out other occasional dividends in the form of supplements to the *Journal*.

Steps are being taken to revise the Constitution and By-laws at this Annual Meeting to permit members to vote for the elective members of the Governing Council, and to have these elections take place by mail, thus offering to every member and Fellow of the Association the opportunity to vote for these important offices. It is my own opinion, in which I believe a majority of Fellows agree, that a broader base for voting franchise is indicated. The A.P.H.A. has an enviable record of democratic participation which should be maintained.

Another matter that is moving forward is the recommendation which the Committee on Eligibility made at its 1946 and 1947 meetings, namely that special consideration be given to liberalizing the policy in effect for cancelling the dues of members of long standing. The Committee on Constitution and By-laws has submitted for approval at this meeting an amendment that would provide for dues exemption of persons who have retired from active duty and who have been affiliated with the Association for thirty years. In addition to this provision, the previous arrangement whereby persons with forty years of membership automatically stop paying dues and receive a special certificate will be continued.

No statement on membership in the Association is complete without mentioning the total number of members, which was 11,531 on September 1 compared with 11,382 on September 1 of last year. A notable increase in new members has taken place in prospect of a new Section on Medical Care. The best membership promotion comes from the word of mouth invitations that members and Fellows express from day to day. The A.P.H.A. is fortunate in having many loyal supporters whose help is much appreciated.

The record of new Fellowship applications is not the only record to be made this year. A total of 164 members and Fellows have applied for Life Membership in the Association, and their names have also been approved by the committee and appear on the list furnished to all members of the Governing Council. This large number of applicants is a result of the offer that was broadcast to all members and Fellows last year enabling anyone interested to apply for Life Membership at the rate of $100 before the new rate of $200 went into effect on January 1. Even at the present rate of $200, Life Membership is a bargain, especially for Fellows, who receive a 6 per cent yield on the investment for the first 17 years, after which it costs them nothing for life.

Applications for Affiliated Society status have been received from the Minnesota Public Health Conference and the Washington State Public Health Association, and the committee recommends that they be accepted. If these organizations are added to the roster of state health associations affiliated with the Association, the total of such organizations will be 29. Correspondence is constantly under way with other state associations interested in such affiliation. In order to be eligible for election, at least half of the active members of the society must be members or Fellows of the A.P.H.A. and the society must show evidence of being a going concern. It has been apparent over the years that the membership provision has prevented certain states from qualifying, but we suggest no change.

Both the Southern Branch and the Western Branch of the A.P.H.A. have adopted revised constitutions this year and the Committee on Eligibility has approved both constitutions as conforming to the standards that have been set up.

Careful attention was given by the committee this morning to the possibility of adding to the Honorary Fellowship list, and the names of Brock Chisholm, M.D., Karl Evang, M.D., and V. Mary Crosse, O.B.E., MD., are hereby presented for the consideration of the Governing Council.

VLADO A. GETTING, M.D., State Department of Health, Boston, Mass., *Chairman*

Professional Education*

IN reviewing the activities and interests of the Committee on Professional Education during the past year, two main currents are apparent to the Chairman, currents emerging from the many smaller streams of detail which represent our daily tasks. The first current is that of increasing interchange of ideas between the C. P. E. on the one hand, the membership of the A.P.H.A. and public health workers at large on the other hand. The second current could be termed briefly: "The C. P. E. represents interests of a growing public health family." The last year has shown us ample evidence that there are newer members in our family who require the same assistance, encouragement and recognition the old established ones have received in the past.

In the light of these two trends, I would like to examine with you the committee's record since last October. One new member was appointed by the Executive Board for a three year term. He is Roy J. Morton, formerly of Vanderbilt University, now at the Oak Ridge National Laboratory. Mr. Morton replaces Ralph Tarbett who had served the C. P. E. faithfully since its beginnings and who died on January 25, 1948. The Executive Board reappointed three members for three year terms: Drs. W. P. Shepard, Gaylord W. Anderson and W. W. Bauer. Since the 1947 Annual Meeting, the committee met once on March 22, 1948, in New York.

In his last Report to the Governing Council, the Chairman of the committee discussed briefly, the divergent views on the training of the various administrators of specialized health activities. Some advocate that maternal and child hygiene, mental hygiene, and cancer control administrators fulfil the various clinical specialty board requirements, while others believe a *reasonable* amount of clinical experience is important but that public health training should be the principal requirement. The Committee on Professional Education favors the second solution and has, during the past year, discharged the subcommittees dealing with the educational qualifications of Maternal and Child Hygiene, Mental Hygiene, and Cancer Control Administrators. In place of their individual reports, a new combined Report on Educational Qualifications of Medical Administrators of Specialized Health Activities is in preparation which will reflect the committee's thinking.

Other new reports in preparation are: Educational Qualifications of Personnel in Vital Statistics and Vital Records; Educational Qualifications of Industrial Hygienists; Educational Qualifications of Dental Hygienists; and Educational Qualifications of Public Health Veterinarians (for which last report, a new subcommittee was appointed during the year). The reports to be prepared for dental hygienists and public health veterinarians are evidence of both currents mentioned at the outset: extending the committee's attention to a growing public health family and increasing the lines of contact between the C. P. E. and the newer members of this family which now turns to the C. P. E. for the type of guidance it has given to old established groups for some time.

The establishment of the Subcommittee on Educational Qualifications of Dental Hygienists also represents part of another development. In establish-

* Report of the Chairman of the Committee to the Governing Council, November 8, 1948.

ing desirable educational qualifications for various groups of public health workers, the C. P. E. used to limit itself almost exclusively to professional groups which require postgraduate training in order to be fully qualified for their work. The Report on Educational Qualifications of Sanitarians which was published in Proposed Form in the July, 1948, *Journal* and which is before the Governing Council for approval, as well as the Report on Dental Hygienists in preparation, deal with workers who rarely have a college degree. In this instance, the unwritten practice of the committee was abandoned since these groups had turned for guidance to the C. P. E. which by now occupies an authoritative position in recommending educational qualifications in the public health field.

A second report before the Governing Council is that on Educational Qualifitions of Community Health Educators which was published in proposed form in the June issue of the *American Journal of Public Health.* Although the Report on Educational Qualifications of Health Educators is only five years old, a complete revision was urgently needed because of the tremendous advances and changes in concepts in this new and important field.

The Proposed Report was generally very well received. The eagerness with which it was expected is documented by numerous letters with some suggestions for minor changes and additions. The Referee, supported by the members of his subcommittee, has incorporated some of these changes into the Proposed Report; the amended version which will probably be approved by the C. P. E. is before the Governing Council. This again is evidence of the democratic interchange of ideas between the committee and those in the field. In this connection it may be well to bear in mind that each Proposed Report is the result of the thinking processes of many minds.

During the past year, 6,600 reprints of the various reports of the Committee on Professional Education were distributed—34,600 inclusive of the *Journal* distribution.

The Executive Board, during the year, approved the appointment of Dr. W. P. Shepard (Dr. Atwater, alternate) Dr. Richard F. Boyd and Dr. V. A. Van Volkenburgh as representatives of the American Public Health Association to the Organizing Committee of the Specialty Board in Preventive Medicine and Public Health. Developments in this direction have been rapid and although this is no longer what might be termed "a C. P. E. affair," the Chairman would like to report briefly on the developments regarding the Specialty Board since the C. P. E. had a strong influence on the events. The Organizing Committee with representatives of the A.P.H.A., the A.M.A., the Association of Schools of Public Health, the Southern Medical Association, and the Canadian Medical Association formally organized in May, 1948, and was incorporated in July, 1948. The by-laws have been approved and the next important step for the Incorporated Board is that of application to the Advisory Board for Medical Specialties. Until this step is taken, applications from possible candidates cannot be acted upon. The Interim Board, formed by the Army, Navy, and U. S. Public Health Service, is awaiting the full functioning of the American Board of Preventive Medicine and Public Health, Inc., and is therefore not examining candidates although it has received a good number of applications from officers in the Services. There is a possibility that our Merit System Service will be called upon to construct written examinations for the new Board.

The next important function of the Committee on Professional Education in connection with the Specialty Board is the establishment of Criteria for the approval or accreditation of residency

experience which would parallel the Criteria for the approval of interneships and residencies established by the A.M.A. The Subcommittee on Field Training, which prepared the original report will submit its recommendations to the Committee on Professional Education.

The Executive Board approved amendments of the accreditation Criteria and granted accreditation to the following universities for the academic year 1948–1949. For the M.P.H. degree: California, Columbia, Harvard, Johns Hopkins, Michigan, Minnesota, North Carolina, Toronto, Tulane, and Yale. For the Dr. P.H. degree: California, Columbia, Harvard, Johns Hopkins, Michigan, North Carolina, Yale. This is the second year Tulane is accredited. Vanderbilt University has discontinued its School of Public Health. This year accreditation was granted to most institutions on the basis of written questionnaires since the committee feels that it is unnecessary to visit each school each year. A summary of the data prepared by Professor Winslow, the Consultant on Accreditation, reveals that the size of the effective budgets and the size of the faculties have generally shown an increase over the previous year. In accordance with this development, the committee may recommend that the Criteria dealing with these requirements be made more stringent. This would provide a safeguard against applications for accreditation by inferior or borderline schools. Some hitherto unaccredited schools have recently expressed interest in accreditation.

The feasibility and desirability of accrediting Master's degrees in health education other than the M.P.H. in schools of public health or outside schools of public health poses an important and difficult problem which is at present being investigated by the committee. Accreditation of graduate engineering curricula is also within the committee's sphere of interest and the committee stands ready to coöperate with the Engineers' Council for Professional Development which has recently started to manifest interest in the accreditation of Graduate Engineering Degrees.

Another phase of the accreditation program is the accreditation of field training areas. The Governing Council on October 8, 1947, approved the Report on Field Training of Public Health Personnel proposed by the Committee on Professional Education. This report contains the following paragraph :" The committee has attempted . . . to establish certain standards which may serve as a guide in the development of field training areas. The committee recognized that these standards are, of necessity, provisional and in many instances reflect a lower quality of service than might be desired. On the other hand, it has been forced reluctantly to accept the fact that many field training areas in all parts of the United States do not attain even these minimum standards." Recognizing the fact that very few field training areas in the United States do come up to the standards of that report, the committee has authorized the drafting of a more realistic set of standards by its Subcommittee on Field Training. The subcommittee met this morning to draft such standards as well as standards for acceptable residency experience. The original three year grant for the accreditation program made available by the Commonwealth Fund is now almost exhausted and other financial resources will have to be found to secure the continuation of this important project. It is felt that this project, which was undertaken at the request of the Association of Schools of Public Health, has not only fulfilled the function of safeguarding a proper level of education for public health workers, but has materially assisted the existing schools in rounding out and improving their programs of instruction.

Another project which is of considerable interest to the program of the schools and of equal interest to the performance of public health administrators is a possible "Job Analysis of Health Officers' Positions" which has been of interest to the C. P. E. for some time. Many public health leaders feel that there is too much discrepancy between what the schools of public health teach and what the health officer actually does. How large a percentage of the curriculum of the schools is concerned with problems of business administration, public relations, community organization and personnel problems? Is it not much lower than the percentage of the health officer's working hours spent on these tasks? This and similar questions might be more reliably answered if the results of a job anaylsis were available. This project which lately was dormant, may be closer to realization because of the active interest of one of our Fellows who was stimulated by the *Journal* editorial on the "Science and Art of Health Administrators" in which this problem was mentioned. Our reader made some practical suggestions for a possible solution—another example that the committee is not and should not be a self-sufficient body.

Much interchange of ideas and actual working relationships is in evidence between the Subcommittee on Salary Study, the U. S. Public Health Service, the State and Territorial Health Officers Association, and other professional groups. At the request of the Committee on Professional Education and the Association of State and Territorial Health Officers, the United States Public Health Service, during the past year, completed a study of salaries of state public health workers and a study of salaries of public health workers in local health units, covering population groups between 50,000 and 250,000. The Subcommittee on Salary Study and the Central Office were helpful in planning and sponsoring the studies, mailing the questionnaires and distributing the completed product. The Clearing House on Public Health Salary Information enjoys the active interest and participation of our readers. The subcommittee is now in the process of working on salary recommendations and on the application for a possible research grant for the purpose of analysis of important basic data inherent in job specifications.

The Merit System Service is looking back on a most interesting and fruitful year. The principal new developments are: an annual service plan together with other arrangements aimed at making the Merit System Service self-supporting; increased promotion of standard examinations; and an increased scope of activity in the field consultation service.

The Annual Service Plan which was announced on July 1 has now been accepted by nine states. The plan provides for a broad and inclusive examination service made available on an annual fee basis to state and city health departments. The service includes the release to the state or city of any number of copies of the available standard examinations, scoring of the answer booklets, analysis of results, and certain other services of interest to merit systems and personnel administrators. The fee ranges from $750 to $4,000 annually and is based on the amount of total funds budgeted for public health. Standard and tailor-made examinations will continue to be released to states and cities not electing to come under the annual service program as well as other agencies.

The National Foundation for Infantile Paralysis Grant for the Field Consultation Service was continued for another year. The field consultant has rendered increasingly useful and appreciated services not only in interpreting the Merit System Service to health administrators in the field, but also in

rendering much needed and expert consultation to merit systems and the personnel management of health departments on problems of classification systems, salary scales, personnel recruitment and selection, and the application of merit system rules. As of October 15, 1948, 35 states, 8 cities or counties, 22 schools of public health nursing, 20 visiting nurse associations and 2 schools of sanitary engineering have used the examination services. During the past year, examinations for various professional groups were prepared for the U. S. Public Health Service and these were taken by over 500 candidates in the United States and Territories as well as those serving overseas. An increasing number of professional fields —keeping pace with the growing public health family—are being supplied with examinations.

Two of the newer members of our growing public health family have recently asked to be included among those for whom educational qualifications have been or are being established. These two new groups are the non-medical administrator in health agencies and the medical-social worker in health agencies. In both instances the suggestions came from the general membership outside the committee ranks, another evidence of the general interest which is being manifested for the committee's work.

I have stated that an increasing amount of interchange of ideas is noticeable between the C. P. E. and all public health workers, and I have illustrated with examples that the committee serves a growing number of professional interests. This is in keeping with an increase in the number of agencies and the expansion of programs demanding the services of an increasing number of professional skills. We all know, however, that supply and demand have not reached an equilibrium and the continuing personnel shortage is directly and indirectly of serious concern to us all.

There are various components to be considered in understanding this continuing problem and they can only be mentioned in passing: the increasing number of public health, medical care, and related agencies using trained personnel; continuing unfavorable salaries; limited capacity of the schools; failure on the part of the faculties to stimulate interest in the public health field among medical, engineering, and nursing students; last not least, ignorance and unawareness among legislators and the general public as to the services of public health agencies and the rôles of public health workers.

The Vocational Counseling and Placement Service continues to report a great discrepancy between the number of applicants and the number of openings on its register. Between March and October, 1948, 212 new openings were registered, but only 48 candidates. Since most of the new candidates are placed much more speedily than the openings are filled, the total openings on the register as of October 1 numbered 766 as against 91 available candidates; a proportion of 8:1. In the past year almost 400 office interviews were held. The Service continues to be the only central clearing house for openings and candidates in the public health field. At present there is no such central clearing house available in the welfare field, and the counselors hold frequent counseling interviews and some correspondence with persons in that field also.

There have been frequent expressions of appreciation for the Counseling and direct placement services on the part of the many persons who come and write to the Association for guidance and advice as well as from employers and candidates. Recruitment on a small scale is of course carried on by the Service but in order to make a dent in the personnel shortage a much more comprehensive program will have to be followed.

The following figures may serve to illustrate the discrepancy between the vacancies in the field and the most important source of supply: the schools of public health. According to our annual tabulation on degrees and certificates granted, during the academic year 1947–1948, the number of M.P.H., D.P.H., Dr. P.H., and M.S.P.H. degrees granted in the United States and Canada by the accredited and a few unaccredited schools was 423. At the very same time there were 447 medical, public health engineering, health educator, and statistician vacancies in the state and local health departments of just 13 states, according to *Public Health Reports*.[1] One year's graduating class then would just about fill vacancies in 13 states *if* all the graduating students were free to go anywhere. However most of them are already employed. Also, such an estimate does not take account of ever-increasing job opportunities in new agencies, the replacements for retired and deceased persons, and for those changing over to other fields.

At the present time there are no funds available for a large-scale recruitment program, not even moderate sums for the printing and distributing of already prepared recruitment pamphlets. This situation should be of supreme concern to all public health workers. It might be well to quote in conclusion a few sentences from a statement in *Public Health Reports*[1] accompanying the tabulation on vacancies mentioned previously:

> Vacancies reported in 1947 were greater than in 1945 in 13 of the 19 categories of positions. Official health agencies will have to face in a realistic fashion, the continued scarcity of trained personnel indicated in these reports if the public is to receive the kind of public health service recommended by competent authorities as a necessary minimum for human welfare. Some of the reasons for this shortage —low salaries, lack of prestige, lack of job security are known. Possibly there are other less obvious reasons. It would seem that the time has come for all concerned to study thoughtfully the problem of recruitment and training of public health personnel with a view to taking definite action to correct the situation".

Research and Standards*

EIGHTEEN years ago, Abel Wolman, Chairman, presented to you the first report of the then recently organized Committee on Research and Standards. In that report, he said:

"A member of an association of national scope may justly expect it to perform for him two major functions. It should provide for him an opportunity to exchange information with fellow workers, and should formulate standards of measurement in those fields where a uniform procedure would facilitate efficient action."

The Committee on Research and Standards is of the opinion that Dr. Wolman's words are still appropriate. It is, however, not a prime responsibility of this committee to provide an opportunity to exchange information with fellow public health workers. The pages of the *American Journal of Public Health* do that. So do the forums of each Sectional session. But even here we do contribute to a valuable exchange of ideas among our 8 subcommittees and the more than 100 members of committees and subcommittees. The strength of the Committee on Research and Standards lies not in having large funds available for research. Rather, strength comes from the pooled knowledge, experience, and interests of its committee members, each of whom has been selected with care.

A principal activity of this committee has been the evaluation, formulation, and preparation of standards of measurement "where a uniform procedure will facilitate efficient action." This does not imply the adoption of standards just for the sake of presenting a rigid formula for action.

* Report of the Chairman of the Committee to the Governing Council, November 8, 1948.

LABORATORY METHODS

Laboratory procedures are bound to reflect the preferences of the individual worker; they will be altered according to the equipment and materials available. However, for any laboratory where a reliable, efficient method must be selected promptly, it is desirable to have access to the proven and tried methods of experts. Likewise, when comparisons between results obtained in different laboratories are made, a common operating procedure must be followed. It is important that these accepted procedures should not be stagnating influences of authority but be constantly maintained as progressive stimuli. That is why the Association, for more than half a century, has been active in the compilation of successive volumes of laboratory methods, now well known as "Standard Methods."

The Ninth Edition of *Standard Methods for the Examination of Water and Sewage* was published late in 1946. Sales of the volume have been brisk so that by November 1, 1948, 6,000 copies had been sold. The results of good editing are shown by the only minor errors discovered in almost two years of use. Steps toward the Tenth Edition have already been taken. The Joint Editorial Board, you will recall, is now composed of representatives from the three responsible organizations: The American Water Works Association, the Federation of Sewage Works Associations, and the American Public Health Association. An organizational meeting of the Board has been held and plans have been prepared for publication, probably in 1951. Walter L. Mallmann, Ph.D., is Chairman of the Standard Methods Committee of the Association working toward the Tenth Edition.

I am also happy to report the publication of the Ninth Edition of *Standard Methods for the Examination of Dairy Products*. This volume went on sale in August, 1948. More than 1,600 copies have been sold already. The Standard Methods Committee under the Chairmanship of A. H. Robertson, Ph.D., which prepared this edition, estimates hopefully that it may not be necessary to publish another revision until about 1955.

You will note the term *Standard* in each of the preceding titles. Such a term is used advisedly. The basic methods comprising the volumes have been time-tested and have reached general acceptance on their merit. The term is also used because in the enforcement of public health laws in the respective fields involved, there must be accepted methods to guide judicial agents and to protect the purveyor. There are two other Association publications that do not warrant the term " Standards " because they apply to fields in which technics are rapidly changing with the advance of knowledge. These methods are not offered as official, completely standardized, rules of procedure. Rather they represent the methods found currently most effective by foremost workers in the subjects.

The first of these is *Diagnostic Procedures and Reagents*. It is now in its Second Edition. A manuscript for the Third Edition is in hand so that a Third Edition should be forthcoming in the near future. This revision, incorporating the numerous changes of the past several years, is being prepared by the Standard Methods Committee on Diagnostic Procedures and Reagents of the Coördinating Committee on Laboratory Methods, Ralph S. Muckenfuss, M.D., *Chairman*.

The second publication represents a venture into a new subject for Association publications. It is *Diagnostic Procedures in Virus and Rickettsial Diseases*, prepared by the Laboratory Section Standard Methods Committee on Diagnostic Procedures in Virus and Rickettsial Diseases, Thomas Francis, Jr., M.D., *Chairman*, and is the first devoted to bringing together accurate details of technics employed in studies of those agents. This volume went on sale in late July and has already reached a wide distribution in the more than 800 copies sold.

In addition, the word, standard, has been dropped from the reports on the Examination of Shellfish.

With the growth of the Association, the diversified interests of its Sections, and the increasing need for a variety of skills with which to approach a broad problem, the possibility exists that numerous studies upon different aspects of the same problem may be in progress without that interchange of information and assistance which could be of inestimable value to the investigating groups. Furthermore, a composite view of the accomplishments would not be readily available to the Association and volumes of standard or recommended procedures, unacceptable to other interested groups, might be offered as Association publications.

Last year your attention was called to a plan designed to afford wider sectional representation on committees preparing laboratory methods while at the same time assuring a more comprehensive review of proposed Association reports and coördination of activities of various sectional committees. The July, 1947, issue of the *American Journal of Public Health* carried the proposed plan. It is my pleasure to report that with the approval of the most vitally concerned Sections, the Coördinating Committee on Laboratory Methods has been established and organized as an integral part of the Committee on Research and Standards. It will be the responsibility of this committee to carry on the preparation of volumes of laboratory methods

already established under the earlier auspices of the Laboratory Section, and to establish subcommittees charged primarily with the duties of review and publication of new laboratory methods when the results of a sectional committee's work indicate the desirability of a published report at a level beyond the ordinary committee report. By this method any Section interested in the proposed volume will be afforded an opportunity for representation on the subcommittee preparing the report. This did not always take place when publications were prepared by a sectional committee. Moreover, by virtue of the closer coöperation between Sections, increased appreciation of mutual interests should be attained and publications will be expedited by furnishing much of the necessary review leading to approval for publication. At the same time it is the purpose of the Coördinating Committee to stimulate sectional committees to exploratory activities, and not to restrict or supersede committees which represent the active interests of the Section. There is firm conviction that this change will contribute valuably to progress.

Under the diplomatic chairmanship of Friend Lee Mickle, D.Sc., seven subcommittees of the Coördinating Committee have already been established and are at work.

One event of the past year is a source of deep regret; that is the curtailment of eleven years of important constructive work done by the Subcommittee on the Hygiene of Housing. Under the imaginative and enthusiastic Chairmanship of C.-E. A. Winslow, Dr. P.H., and the patient and constructive service of its Technical Secretary, Allan A. Twitchell, this committee has placed housing and health squarely before all categories of public health workers, town and city planners, architects and numerous citizens' committees. You are familiar with the earliest publications of the committee. *An Appraisal Method for Measuring the Quality of Housing*, published in two parts, has had wide circulation. Early this year the first of a three-part series on *Standards for Healthful Housing* was published. The title of the report is "Planning the Neighborhood." The second part on dwelling space and occupancy standards is in the final editorial state. In addition to preparation of these reports, the staff of the committee has worked with the U. S. Public Health Service in establishing a training course on appraisal technics at the Communicable Disease Center. Assistance has also been given to the Bureau of the Census in preparation of the 1950 Census of Housing. Although a shortage of funds must necessitate markedly lessened activity by this committee, continued support by the Milbank Memorial Fund should permit a carrying on of work until completion of the Standards for Healthful Housing series sometime in 1949. I am sorry to record this pessimistic report.

The most widely distributed publication of the Committee on Research and Standards is the report on the *Control of Communicable Diseases*. The Sixth Edition has been translated into several languages, its sales are numbered in six figures and the World Health Organization has exhibited a deep interest in its being available as an international contribution. The Subcommittee on Communicable Disease Control, again under the effective Chairmanship of Haven Emerson, M.D., has been preparing a Seventh Edition of the report. An indication of the enthusiasm with which this committee is attacking its task is the two day session held prior to the Annual Meeting for actual revision of a preliminary draft. The Seventh Edition should be ready for publication not later than 1950.

The 1947–1948 *Yearbook* carried in it a copy of a proposed technic for the bacteriological examination of food utensils. This had been prepared by the Subcom-

mittee on Food Utensils Sanitation of which Walter Tiedeman is *Chairman*. The Committee on Research and Standards accepted the report with the recommendation that it be adopted as an Association report. Your reply by means of a mail vote resulted in 90 votes for approval and no dissenting vote. The subcommittee is continuing its study of the sanitation of food utensils.

Your committee has been aware of the growing interest in various aspects of the sanitation of the atmosphere. For several years a Subcommittee for the Evaluation of Methods to Control Airborne Infections was active and rendered valuable reports on the current status in this field. Several committees of the Engineering, Epidemiology, Industrial Hygiene, and Laboratory Sections have also been active in studying other segments of the problem of air purification. In order to provide a coördination of all interests at an Association level our subcommittee was reorganized and renamed the "Subcommittee on Air Sanitation." Alexander D. Langmuir, M.D., the new *Chairman*, will have had his committee in session during this Annual Meeting for the purpose of charting a program for next year. Their purpose is in no way to supplant existing sectional committees; rather, it hopes to bring together their findings through sectional representatives on the new committee and to cover aspects needing study in which sectional committees may not be involved.

As you are probably aware, the Sixth Revision of the *International List of Causes of Death* is an accomplished fact. To this list of causes of death has been added a classification of diseases and injuries. Although the Association did not participate officially in the preparation of these lists, it was represented in that the Chairman of our Subcommittee for the Sixth Revision of the *International List of Causes of Death*, Edward S. Rogers, M.D., was a member of the United States Subcommittee working with the international committee in the preparation of the Sixth Revision. Since United States participation was through official agencies of the government, it would seem that our subcommittee can continue to serve a useful purpose by observing and experimenting with the use of the *Lists*. This should assure a means for carrying to the official agencies the conclusions and recommendations of the professional public health group. Our committee will discuss these functions at its meeting here this week.

During our meeting in March the following motion was adopted:

> "That the Subcommittee on Morbidity Registration and Statistics be requested to conduct appropriate research so as to establish a practical pattern of a county and city mechanism for morbidity reporting and for public health statistics which are based on a current, up-to-date knowledge of the characteristics and distribution of the population."

Lowell J. Reed, Ph.D., *Chairman* of the subcommittee, and his committee have been asked to assume this as one of their tasks.

The Committee on Research and Standards has also been represented on committees of the American Standards Association. I shall comment briefly on one. Public health interest in plumbing is quite generally accepted. Two members of the Association have been very actively representing the professional public health worker on the ASA committee preparing a plumbing code. This committee is known as A40. The American Public Health Association is one of the two sponsoring organizations. Preparation of a code that could satisfy all members of A40 proved extremely difficult. It is reported, however, that the text of the code has been agreed upon and now is ready for submission to the ASA for the next routine steps toward adoption. This code is awaited eagerly by people in the field.

For more than ten years the American Public Health Association has been a

participant, along with several other professional societies, in the preparation of a *Glossary of Water and Sewage Terms*. Originally we had two subcommittees active in this endeavor, but last year Sol Pincus was appointed to carry on the work of both. He reports completion of the editorial work on the *Glossary*. All that remains now before actual printing begins is a settlement of the financial arrangements under which the report will be published.

The Committee on Research and Standards is deeply appreciative of its associated committees which constitute the continuing activities under its auspices; it is also deeply aware of its responsibility for maintaining the high standards they have already set. Through their persistent endeavors we can look with confidence to the proper fulfillment of the committee's responsibilities in the formulation of standards of measurement for the Association.

On the other hand, the present committee has considered in detail the functions of Research and Standards in relation to research. There has been more progress in medical research during this century than in all previous history. Funds are more readily available and the public is more conscious of the need for investigation, both fundamental and applied. An association of this size must provide a constant urge to all divisions of public health to desire controlled scientific evaluation of their problems. It appears that a tendency has developed to consider this committee as a compiling and reviewing board with but a limited responsibility for the initiation and projection of research. If the editorial were the only function of the committee it might preferably give way to the Coördinating Committee. This concept is not in complete agreement with the objectives originally assigned to the committee nor with the desires of the present committee. The studies on the Hygiene of Housing are a striking example of progressive investigation under the committee's auspices. It is believed that other explorations should be initiated and prosecuted when it seems desirable for the advancement of the public health and the good of the Association. Although it is unlikely that the committee as such would undertake actual operation of a research project, there seems no reason why it should not if a suitable occasion should arise. There is a strong conviction that this committee should be active rather than passive in the development of research; that it should critically review research work in progress, suggest new research, attempt to interest suitable agencies in conducting work, and when desirable to seek support for it. Even the interpretation of what is meant by the "technical" branches of public health service is subject to a broad definition, for in many instances a frank approach by the experimental method will result in the testing of impressions and the establishment of data which cannot be obtained by philosophic agreement, compromised opinions, and the weight of authority. Just as the field of social sciences suffers from an unwillingness to apply scientific methods because of the scope of the problem, so may many problems in public health be delayed from reaching proper conclusions by reluctance to undertake sizable experiments. It is my belief that this committee should strive to overcome that defect and that this Association should lead the way in submitting important questions to actual test. The success of the "methods" activities has been due to their reliance upon the scientific evaluation of their procedures. Untested authority is valueless.

In order to clarify its situation the committee at its meeting of March 6 requested that the terms of reference be changed to state that it shall be responsible for initiating, conducting, pro-

moting, coördinating, and reviewing research and for the development of standards in the technical branches of public health. In this sense it will strive to encourage the undertaking of investigations by Sections or other interested groups; to suggest problems which might properly come within their purview; to bring together independent but interested investigators for cross-fertilization of ideas leading toward the solution of a problem. It should ask for suggestions through which this or other Association committees could contribute effectively to the advancement of knowledge. Research should not be limited to problems of immediate applicability; it should not be a china egg over which a misguided hen sits and clucks. At the same time we should not make a fetish of the word "research."

In order to gain momentum for this point of view, the committee has asked the different Sections to furnish a list of problems with which they may be engaged, to suggest problems which they would like to see implemented, and to invite members of sectional or other committees to tell the Committee on Research and Standards of their activities. It is believed that problems which may come to the committee can be referred to the Sections in whose channels of interest they may lie. It is also believed that professional assistance in the central office should be provided for the Committee on Research and Standards so as to review numerous committee reports, study technical projects of the Sections, and serve as technical adviser to committees meeting independently. It is also suggested that the Sections spend some time at this Annual Meeting in consideration of problems which should be submitted to investigation. In response to a questionnaire sent to each Section Secretary, eleven replies were received. Most of them stated that they were not engaged in any research although this may be a matter of interpretation. Four Sections made specific recommendations as to research. These will function as a nucleus for considerations by the Committee on Research and Standards at its meeting.

Several referees were appointed at our last meeting to study special problems that have arisen recently. Their reports and recommendations will be submitted at our meeting on Wednesday evening. You will be interested in knowing the subjects involved.

At our last meeting, in Atlantic City, you were presented with a proposed resolution calling for approval of the topical application of fluorides in the prevention of dental caries. At the time you thought the evidence available did not warrant definite action, and so this committee was asked to explore the subject. The evidence has been undergoing a thorough review since March, 1948, and a recommendation should be available for you following our meeting.

Four technical reports of various Sections were referred to referees to determine need for revision in view of technical changes which may have occurred since publication. One of them, *Recommended Practice for the Design, Equipment and Operation of Swimming Pools and Other Public Bathing Places,* is now being revised and will probably be considered during our meeting. If favorable action is taken you will probably be asked by mail ballot to vote on its acceptance as an Association report. It has already been accepted by the Conference of State Sanitary Engineers, cosponsor with the Association.

Another referee is considering an invitation to participate in an international committee for enteric phage typing. Still another is exploring the need for an authoritative manual for the guidance of administrators of isolation hospitals. Considerable data have already been collected describing policies now in use at isolation hospitals.

I have briefly reviewed the accom-

plishments and the burgeonings of the Committee on Research and Standards. It is my great pleasure to point to the obvious: the fact that they derive from the interest and efforts of many participants. I hope, too, that this statement will reflect the spirit of the committee and its desire to fulfil its assignments and to advance the field of scientific learning in public health.

THOMAS FRANCIS, JR., M.D.,
University of Michigan, Ann Arbor, Mich., *Chairman*

The Control of Typhoid Carriers*

Committee on Administrative Practice

WITH the elimination of waterborne, milk-borne, and other foodborne epidemics of typhoid fever, brought about by the continuous improvement in sanitation, the time has arrived in many areas when the residuum of typhoid fever is coming almost entirely from typhoid carriers. These carriers are those of the former victims of typhoid fever (one out of 30) who have never ceased to excrete the organisms.

Unfortunately, only a small number of these carriers are known to health agencies because at times in the past release cultures were either not obtained or were examined in laboratories whose methods failed to disclose the typhoid bacilli. In many states the estimated number of living typhoid carriers is 25 to 50 times the number of cases of typhoid fever reported in any single year. The chronic carriers left over from former days of high prevalence are, therefore, much more important sources of new cases than the current cases of the disease. This is particularly true since none of these carriers, except those on registers of health departments, know that they are a danger to their relatives and associates.

In those states where typhoid fever has been brought to a very low level, it is estimated that more than one-half of these carriers are over 60 years of age. It is evident that within a few years the typhoid fever arising from chronic carriers is destined to drop to even lower levels.

In the meanwhile, if those carriers who are producing our current cases can be discovered and put under supervision, a considerable contribution can be made in further reducing the number of cases.

In order to reduce the frequency of the chronic carrier as a source of new cases, the following procedures are recommended:

LIST OF CHRONIC CARRIERS

The health department of each state, territory, and province should maintain a list of all permanent typhoid carriers within its jurisdiction. The name of any person placed upon this list should not be removed from it until his death, or until he is found no longer to be a carrier under criteria outlined below. Each person on the list should be visited at least semiannually by a representative of the state, territorial, or provincial health department, or by a well trained person in a local health department. It should be recommended or required that all persons living in a household with a typhoid carrier, except those who have had typhoid fever, be given typhoid vaccine. The primary course of vaccine should consist of three subcutaneous doses of 0.5 ml., 0.5 ml., and 0.5 ml. at intervals of not less than a week apart, followed by annual stimulating doses of 0.5 ml. subcutaneously, or 0.1 ml. intracutaneously.

DEFINITION OF A CHRONIC CARRIER

A chronic typhoid carrier is a person who has not suffered from typhoid fever within the previous 12 months and who persistently discharges typhoid bacilli.

---

* Report of Study Group.
STUDY GROUP ON TYPHOID FEVER OF THE SUBCOMMITTEE ON EVALUATION OF ADMINISTRATIVE PRACTICES.

Such carriers usually fall into the following three groups:

1. Convalescent cases of typhoid fever who continue to excrete typhoid bacilli for more than 12 months after onset.
2. Persons discovered in routine laboratory examinations or in epidemiological investigations to have a history of an illness resembling typhoid fever more than 1 year previously, or who have apparently been sources of other cases of typhoid fever, and who show stools positive for typhoid bacilli on two successive specimens.
3. Persons discovered accidentally to be harboring typhoid bacilli, even though there is no history of a presumptive typhoid illness, who continue to excrete typhoid bacilli for 2 months after discovery.

REGULATIONS REGARDING TYPHOID CARRIERS

Each state, territory, and province should have regulations prohibiting convalescent and chronic carriers from preparing food for the public, including particularly the handling of milk and milk products on farms or in milk plants. Unless the carrier is coöperative, intelligent, and can be depended upon to observe proper precautions he should not be allowed to care for the sick or for children. Each carrier should receive instructions or be asked to sign an agreement that he will not prepare food for any person except members of his own household who have been vaccinated against typhoid fever within 2 years; that he will wash his hands thoroughly with soap and water after each visit to the toilet; that in case of sickness or accident he will inform the physician, nurse, or other attendant that he is a typhoid carrier; and that he will inform the health department in advance of each change of address.

Typhoid carriers should be told that as long as they live up to their agreement, the fact that they are carriers will be kept confidential. In notifying a local health agency that a carrier has moved into its jurisdiction, this confidential relationship should be emphasized.

SEARCH FOR CARRIERS

1. *Convalescents*—A very productive method of discovering carriers is to follow current cases of typhoid fever through convalescence with periodic stool and urine cultures. Three to 5 per cent of convalescents will continue to excrete organisms for more than 12 months. Those who are shown by repeated laboratory examinations to be harboring typhoid bacilli and excreting them constantly or intermittently for more than 12 months, should be regarded as chronic carriers and placed upon the permanent carrier list. Less administrative effort is spent in finding carriers by release cultures than by any other method. Moreover, they can be kept under continuous supervision so that they will not be responsible for other persons becoming infected. Those who escape supervision often are found later to be a source of a case of typhoid fever.

2. *Epidemiological Investigations*—A most fruitful method of discovering chronic carriers is to uncover individuals responsible for current cases. In some instances, as simple a method as the routine culturing of adult members of the household will point to the carrier. Children and adolescents are unlikely to be carriers unless there is a history of illness resembling typhoid fever. Cases of the disease occur most frequently in a new person who is introduced into a household where there is a typhoid carrier, or when a typhoid carrier is introduced into a new household. It is often necessary to extend the investigation outside the immediate household to discover the carrier. Since a majority of typhoid carriers are over 50 years of age, carriers can be discovered occasionally by culturing the older members of households where a typhoid fever patient has been visiting recently, or by culturing the older persons among visitors who have recently been in the household of the ill person. Phage typing

can be used to verify that the carrier under suspicion is responsible for the case or outbreak.

3. *Examination of food handlers*—A less productive method of discovering chronic typhoid carriers is to examine stool specimens from persons working as food handlers. Such examinations should be selective and not routine. Hundreds of examinations can be made without finding a single carrier. It is wise to obtain stool specimens from food handlers who give a history simulating that of typhoid fever.

4. *Examination of bile from cholecystectomies*—The routine examination of bile from gall bladders removed at cholecystectomy can be used as an additional method of discovering carriers.

Since a large proportion of chronic carriers will show positive or partial agglutination tests, in areas where typhoid vaccine is seldom given, Widal reactions performed upon contacts of typhoid fever cases give useful information. Any persons who show a positive or partial reaction and who have no history of having received typhoid vaccine should be required to submit at least two stool specimens, if the first one fails to disclose typhoid bacilli. It must be borne in mind, however, that many carriers do not show agglutinins in significant titers. In areas where typhoid vaccine is widely given, the Widal is of little value, but agglutination tests with VI antigen have been found to be useful in pointing to typhoid carriers. There is no doubt as to the authenticity of specimens when blood samples are taken for agglutination tests.

All laboratory examinations for the discovery and control of carriers should be performed in the laboratory of the state, territory, or province, or in other laboratories approved for enteric examinations.

CRITERIA FOR THE CURE OF CARRIERS

It is unusual to find an exception to the rule that those individuals who continue to be carriers of typhoid bacilli for more than 12 months after the onset of typhoid fever will be carriers for the rest of their lives, unless the focus is removed by operation. No drug or antibiotic has yet been found which gives consistent results in eliminating typhoid bacilli from such foci. Only a few spontaneous cures without operation have been recorded, and any such reported instances should be thoroughly verified by appropriate laboratory tests before declaring the person cured.

CURE OF CARRIERS BY CHOLECYSTECTOMY

Since the focus in most instances is in the gall bladder, a high per cent of carriers can be cured by cholecystectomy. Such an operation should not be recommended or undertaken until it has been determined by examination of bile obtained by duodenal tube that the person is probably a gall bladder carrier. An examination of the contents of the gall bladder after operation will confirm that it is the focus. In most instances the gall bladder of a typhoid carrier will contain stones.

A typhoid carrier who has had his gall bladder removed will often continue to excrete typhoid bacilli for several days, and in some instances for 1 to 6 months after operation. When the stool specimens become negative, monthly specimens should be obtained until 12 months have elapsed since the first negative specimen. Final release should be dependent upon the failure to find typhoid bacilli in bile obtained by duodenal tube. and the examination of the next two stool specimens after giving magnesium sulphate through the duodenal tube. Before reporting the bile specimen as negative, the laboratory should verify that the specimen obtained really consists of bile.

The only deviation from this policy of requiring cholecystectomy for release should be for those persons placed upon

the carrier list in the past upon insufficient evidence. Some of those who were placed upon the list less than 1 year after onset may be found to have ceased to excrete organisms. In such instances a series of negative stools should be required which on laboratory examination are found not to contain typhoid bacilli. At least one or two of such stool specimens should be proved to be authentic by obtaining the specimen under supervision, or by giving lycopodium in the presence of a representative of the health department, followed by finding the lycopodium granules microscopically in the specimen submitted.

Carriers found to be harboring the bacilli in the kidney or other location may be cured if the focus can be removed. Criteria for cure depend upon examination of the appropriate secretion or excretion which formerly contained the organisms.

SALMONELLA CARRIERS

Similar procedures should be followed in handling persons found to be carriers of salmonella organisms. The salmonella species which produce a bacteremia will usually localize in the gall bladder. Those which produce only gastroenteritis may establish a focus elsewhere. Previous bile drainage is therefore quite important before operation is recommended.

SHIGELLA CARRIERS

Permanent carriers of Flexner and Sonne bacilli are very seldom encountered. Procedures similar to those recommended for typhoid carriers can be followed if a permanent shigella carrier is found. The focus would probably not be in the gall bladder.

(This report was completed before aureomycin was found to be effective in treating patients and carriers. If the favorable results of aureomycin are corroborated by subsequent studies, procedures for carrier control may have to be substantially modified. ED.)

Coördinating Committee on Laboratory Methods*

Committee on Research and Standards

THIS is the first annual report that the Coördinating Committee on Laboratory Methods has been privileged to present. Since its establishment at the 1947 Annual Meeting of the Association it has functioned under the wing of the Committee on Research and Standards, one of the Standing Committees of the Association.

The Coördinating Committee on Laboratory Methods supersedes the Coördinating Committee on Standard Methods which, after its inception in 1933, had a long and creditable record of accomplishments under the auspices of the Laboratory Section, during most of this time under the very able leadership of Colonel Arthur Parker Hitchens. The objectives behind the establishment of the Coördinating Committee on Laboratory Methods were to establish a liaison between the work of the committees preparing laboratory methods and the several Sections of the Association having an interest in the use or the application of any of the various laboratory methods which the Association may foster, and to reduce the time elapsing between the preparation of manuscripts and their publication.

The personnel of the CCLM was selected by the Committee on Research and Standards and appointed as soon as possible after the 1947 Annual Meeting. The interests of all of the Sections having a stake in laboratory methods seem to be well represented in the personnel of the committee. An organization meeting of the new committee was held in the City of New York on March 6, 1948. At this meeting much time was devoted to discussion of the proper fields of activity for the committee and to organization of the work in relation to the Association and its Sections as well as to other interested groups.

It was a decision of the committee that CCLM should deal primarily with laboratory activities that are the concern of more than one Section of the Association. It was the consensus of the group that a committee working on a specific laboratory problem should have representation from all Sections of the Association concerned with the activity under consideration and that appointments to membership on the working laboratory committees should be made in consultation with the Section Council of the Section with which the prospective appointee is affiliated, as is provided in items 1.2 and 2.32 of the "Outline of Organization." It was visualized that some Sections may continue their own committees on methods or laboratory procedures which do not affect the interests of other Sections of the Association.

Up to the present time the CCLM has not established committees to function in some of the fields previously covered by the Coördinating Committee

* Report of the Chairman.

COÖRDINATING COMMITTEE ON LABORATORY METHODS.
Organized under the Committee on Research and Standards 1947.

on Standard Methods of the Laboratory Section. Examples are the biology of the laboratory animal and the field of examining germicides and antimicrobial agents. The committees named below have been established:

Standard Methods Committee for the Examination of Water and Sewage
Standard Methods Committee for the Examination of Milk and Milk Products (Including Frozen Desserts)
Committee for the Examination of Shellfish
Committee on Diagnostic Procedures and Reagents
Committee on Therapeutic and Diagnostic Biological Products
Committee on Virus and Rickettsial Diseases
Committee on Microbiological Examination of Foods

Below in this report are presented brief summaries of the activities of these seven committees for the short period of time they have existed under the auspices of CCLM.

Standard Methods Committee on Examination of Water and Sewage—

No report to the Coördinating Committee has been received from the chairman of the committee, Dr. Walter L. Mallmann. The most recent edition of *Standard Methods for the Examination of Water and Sewage* was the 9th, published in 1946. Both the CCLM and the chairman of the water and sewage committee were approached early in the year by the Association's representative on the joint committee of the three participating associations (the American Public Health Association, the American Water Works Association, and the Federation of Sewage Works Associations) with the request that the committee become immediately active in the preparation of material for a 10th Edition of the report. We were informed that the other two coöperating associations have done considerable work toward that edition and await the active participation of our committee. Consideration will be given to this matter at the meeting of CCLM that is to be held in connection with this Annual Meeting.

Standard Methods Committee for the Examination of Milk and Milk Products (Including Frozen Desserts)—

An excellent report of the work of this committee during the year has been submitted by the chairman, Dr. Archie H. Robertson. The 9th Edition of *Standard Methods for the Examination of Dairy Products* became available in August, 1948. Much improved in content and offering up-to-the-minute laboratory procedures for the examination of milk and a variety of milk products, the book is decidedly easier to use than were previous editions, because of the introduction of a simple cross-reference system. The reader will discover another innovation in that all of Chapter I of this volume is given over to a well arranged discussion of the applications and interpretations of the laboratory methods on milk and milk products that in previous editions were scattered throughout the text. This chapter is complete and well arranged, and contains much new material. Accordingly, this edition should become a valuable reference book for the health official or sanitarian in determining tests applicable to a given milk supply and in evaluating the laboratory findings. The chapters containing specific directions for laboratory procedures, now not interspersed with comments regarding interpretation, become much more readily intelligible to the laboratory worker.

The CCLM has authorized the Committee on Milk and Milk Products to publish Chapter II of the above mentioned volume as a paper-bound reprint. That chapter dealing with "Microbiological Methods for Milk and Cream" is the portion of the book most widely used in laboratories and by students and others. The reprint will be

available soon at a reasonable price.*

A subcommittee of the Committee on Milk and Milk Products has in manuscript a revision of Chapter II in a so-called "cook-book" style. This is an attempt to meet a demand from teachers of bacteriology for a simple laboratory guide at a low price. The little circular should play a part in bringing about uniformity of instruction among students, and the instruction they receive will be based on standard method procedures. The CCLM will soon be asked to approve this manuscript.

The Committee on Milk and Milk Products is already actively at work studying proposed revisions to improve even further the directions in a forthcoming 10th Edition of the milk and milk products methods report. Chief among the projects under study is a proposed modification or replacement of the currently recommended plate-count medium which is said to be simpler to prepare and which possibly may grow more colonies. Preparatory to revising the next edition the committee is having papers presented at this Annual Meeting on modified staining procedures for the direct microscopic method. Moreover, the committee is coöperating with the Association of Official Agricultural Chemists in the hope of securing full uniformity in the procedures for determining sediment, making phosphatase tests, and carrying on other tests in which both Associations are interested.

Committee on the Examination of Shellfish—

This committee last presented a report in the September, 1947, issue of the *American Journal of Public Health.* The chairman, James Gibbard, reports that during the year the only activity of the committee has been through correspondence between the chairman and the members. The committee seems to feel that the recommended procedures so far formulated are only a part of a much larger job, and it is looking forward to a publication dealing with the many laboratory aspects of the shellfish problem; namely, bacteriological procedures, chemical methods so far as they are applicable, the biology of the several species of shellfish, shellfish poisoning, enteric infections traceable to shellfish, sanitation of shucking and handling establishments, shellfish culture, and related topics.

Committee on Diagnostic Procedures and Reagents—

This committee, under the chairmanship of Dr. Ralph S. Muckenfuss, has been very active during the year in preparing the 3rd Edition of *Diagnostic Procedures and Reagents.* The earlier editions of this manual of technics for the laboratory diagnosis of the communicable diseases have had wide acceptance, and the 2nd Edition particularly has become a standard textbook in most diagnostic laboratories, large and small, throughout the territory served by the Association. The 3rd Edition is being revised to include a new chapter on Determinations of Levels of Antibiotics and Response to Bacteria by Caroline Falk, and one on Rh Testing by Dr. Philip Levine. In the main the same authors have been retained to revise and bring up to date the technic for the disease to which they were previously assigned although in a few instances the name of a new author of a chapter appears. The chapters on virus and rickettsial diseases, including those on Typhus and Rickettsial Fevers, Lymphogranuloma Venereum, and Rabies, were referred to the Committee on Virus and Rickettsial Diseases and appear in the manual published by that committee. The 3rd Edition of *Diagnostic Procedures and Reagents* is now in manuscript form and will very likely

* Since this report was presented, the reprint has been made available for 75 cents.

be submitted to the CCLM at this Annual Meeting for approval.

Committee on Therapeutic and Diagnostic Biological Products—

This is a new committee established to devote attention to diagnostic as well as to therapeutic biological products. It is not anticipated by the CCLM that it will be the intention of the new committee to prepare an extensive manual of tests to determine the efficacy of biological products in general. It seemed to the Coördinating Committee at its organization meeting that the functions of a committee dealing with the several aspects of therapeutic and diagnostic biological products would of necessity extend beyond the field of work of any one Section. It seemed wise to establish a committee in this field and request it after study to recommend to the CCLM what may be necessary in the way of activity in this direction by the Association. The chairman of the Committee on Diagnostic and Therapeutic Biologic Products, Dr. John T. Tripp, has reported to the CCLM that he has been active with the members of his committee in studying the field of activity of the new committee and that he is calling the group together for its first meeting. A report is expected to be forthcoming during this Annual Meeting of the Association.

Committee on Diagnostic Procedures in Virus and Rickettsial Diseases—

This committee, under the chairmanship of Dr. Thomas Francis, Jr., is to be complimented on bringing out in May of this year the first edition of *Diagnostic Procedures in Virus and Rickettsial Diseases,* a 347 page laboratory manual by a selected group of experts that is the first adequate compilation of laboratory procedures in its field. The wide sale that the book has already had is indication of the need for and the general acceptance of the volume. The preface states that no pretense is made that an exhaustive review of all possible technics has been produced or that the procedures have been standardized to the satisfaction of all laboratory workers. Instead, the methods are presented by the committee as those most generally found dependable by the active workers in this relatively new field of laboratory activity. It is the feeling of your Coördinating Committee that the Association and its members will be as proud of this publication, in the several editions through which it is likely to appear, as it has been of the widely accepted companion publications of the Association in the field of laboratory methods.

Committee for the Microbiological Examination of Foods—

Since the Committee on Microbiological Examination of Foods was selected by the CCLM as one of the subcommittees to function under its guidance, the activities of this committee, have been, according to the report of its chairman, Dr. Harry E. Goresline, largely devoted to consolidation of the work of previous years. Reprints of all previously developed methods that had been published from time to time were obtained and the methods described therein are being revised by the committee to get them in line with recent developments, to present them under a more uniform pattern, and to eliminate duplication among them. A preliminary set of Methods for the Microbiological Examination of Dehydrated Fruits and Vegetables has been developed during the year and presented to the CCLM for approval. The chairman has reported that the work of bringing these methods together was largely that of Matthew E. Highlands, a member of the committee. Work is also being done by the committee in the relatively new field of pre-cooked frozen foods. The committee is hopeful

that a manuscript of a manual for the microbiological examination of foods will before too long a time become an accomplished fact.

Aims of the Coördinating Committee—

As the Coördinating Committee on Laboratory Methods has been functioning less than a year it is hoped that the Committee on Research and Standards, the members of the Association and the Section Councils of the several Sections will consider this as a progress report made too soon after the formation of the committee for much to have been accomplished, especially since only one meeting could be held for the purpose of organizing and apportioning work to subcommittees. The committee hopes to function so as to relieve the Committee on Research and Standards of a multiplicity of detail in respect to laboratory methods.

A major goal is the publication by the Association of the kind of laboratory methods that will continue to keep the American Public Health Association in the forefront of the public health laboratory field. To attain that goal close coöperation will be sought not only with the several Sections of the Association that have interests affected by the preparation or use of laboratory methods but also with other associations and organizations interested in the publication of laboratory methods. The Coördinating Committee on Laboratory Methods solicits assistance and suggestions from all sources to aid it in its important task.

Standard Methods for the Examination of Dairy Products*

Committee on Research and Standards

YOUR Chairman is happy to report that copies of the Ninth Edition of *Standard Methods for the Examination of Dairy Products* became available late in August, 1948. The introduction of a simple cross-reference system for the thirteen chapters, and the carefully organized arrangement of the applications and interpretations of quality tests in Chapter 1, makes Standard Methods distinctively useful both to administrators and to laboratory workers.

By authorization of the Coördinating Committee on Laboratory Methods, Chapter 2, on Microbiological Methods for Milk and Cream, will be offered for sale as a paper-bound reprint.† While administrators, laboratory chiefs, heads of college departments and libraries will want copies of the complete edition, many workers actually engaged in the examination of milk and cream samples by one or more of the four recognized routine procedures will want copies of the separate. Many teachers of dairy sanitation will want their students to have copies as a reminder after graduation that there is a Standard Methods and an American Public Health Association.

Dr. Samuel R. Damon, as Subcommittee Chairman, has nearly completed a so-called "cook-book" style of revision of Chapter 2. The intent is to provide teachers of bacteriology with a simple laboratory guide, which in turn will establish greater uniformity of instruction among students. Like the separate referred to above, reprints of this will be made available at a reasonable price to laboratory workers and to students taking college courses. The title of the report will be "Microbiological Examination of Milk and Cream, Laboratory Outline."

Because of the inconvenience of incorporating skim milk solids uniformly in the tryptone glucose beef extract agar plating medium and the tendency for these solids to precipitate when the medium is melted before pouring the plates, considerable thought has been focused on replacing the officially recognized medium with one which does not require the addition of skim milk or skim milk solids as such. Any substitute medium should provide equally as good growth of bacterial colonies as, if not better than, the present medium provides. The standard plate count obtained thereon should be essentially the same as that obtained on the accepted official standard medium. Reports of progress on this project will be made during the week.

New and/or modified staining procedures for milk films used in the direct microscopic method have been proposed. During the week, reports will be presented on these staining techniques.

The present practice of using a rinse method for determining the practical sterility of certain types of dairy equipment has been questioned. Studies are now in progress to determine whether or

* Report of the Committee to the Coördinating Committee on Laboratory Methods. First published report 1910.

† Now available for 75¢.

not the swab contact technique should not replace the rinsing procedure when testing milk cans for their sterility.

The method for Sediment in Milk, appearing in Chapter 9 in *Standard Methods,* is being considered favorably by the Association of Official Agricultural Chemists for inclusion in their *Book of Methods.*

Because of problems encountered with the melting of frozen dessert samples before removing representative test portions therefrom, a subcommittee, with Dr. Leon Buchbinder as chairman, is studying the details of an optional procedure for weighing test portions of the unmelted frozen dessert directly into dilution bottles.

The Association of Official Agricultural Chemists at their meeting in October, 1947, authorized the deletion of all previously recognized methods for the determination of residual phosphatase in pasteurized milk, and in place thereof voted to accept the Sanders-Sager method. A quotation from the February, 1948, issue of their *Journal,* page 82, follows:

> The following method was adopted as official, first action, for fluid milk and cream, cheddar type cheese, and soft uncured cheeses, and as tentative for other types of cheese, ice cream mix, sherbet mix, chocolate-flavored milks and skim milk, butter, sweet-cream and cultured buttermilks, fermented milks, goats' milk, cheese whey, and concentrated milks.

For years the New York State Department of Health method and one or more modifications of the New York City Department of Health method for phosphatase have been officially recognized by both the American Public Health Association and by the Association of Official Agricultural Chemists. The deleted procedures are well known and have been used successfully to correct faulty pasteurization practices as to fluid milk and cream. At the time of approving the manuscript for the Ninth Edition of *Standard Methods,* the Sanders-Sager method, originally developed for determining residual phosphatase in cheddar type cheese, was likewise in the manuscript stage. Although the original Sanders-Sager method requires many special modifications according to the product examined, it does have desirable features not possessed by any of the other methods. The Ninth Edition contains a description of this method as it applies to hard type cheese only.

As many of you know, we are working coöperatively with the Association of Official Agricultural Chemists to the extent that with their permission we are quoting from their *Book of Methods* many of their chemical procedures for analyzing dairy products. In this case, we cannot ignore their approval of the Sanders-Sager procedure with its wide application. In order to give an opportunity to compare the several methods, multilithed copies of the Sanders-Sager method may be obtained by addressing a request to the American Public Health Association.

Plans are now under way by the AOAC to enlist the help of collaborators in public health laboratories early in 1949 to compare the phosphatase method commonly used on fluid milk and/or cream in their laboratories with the Sanders-Sager method. Many laboratories in which the New York State Department of Health method and/or the New York City Department of Health Laboratory method are now used will want to take an active part in the collaborative work.

Dr. E. H. Parfitt reported that in 1944 representatives from The Dairy Industry Committee (Washington, D. C.), the International Association of Milk and Food Sanitarians, and the U. S. Public Health Service joined in inaugurating an industry and country-wide program to establish minimum sanitary standards for dairy equipment. The purpose was to stabilize the prac-

tices of the equipment manufacturers and at the same time to assure that an increasing proportion of the dairy equipment sold will be suitably designed. Although the acceptance of standards is voluntary, the accomplishments to date disclose almost unanimous acceptance by fabricators and buyers of equipment.

The coördinating program has served to guide buyers after the war in the replacement of old and worn equipment with new equipment acceptable in all markets for all types of dairy products, and to assure that standards in one city will be less apt to conflict with standards in another city. Much of the equipment is made of stainless steel, which offers potentially longer usage, and in turn creates the need for more care in designing the same.

Since 1944, standards have been promulgated for holding tanks, weigh and receiving tanks, pumps, homogenizers, and fittings used on milk pipe lines. In 1949 the committee hopes to complete its standards for transportation tanks, electric motors, can washers, heat exchangers of the plate, tube, and surface types, milk filters, milk pails and strainers, and milking machines.

The benefits derived by the dairy industry may serve as a guide for other branches of the food industry, because it has been demonstrated that proper design results in increasing ease with which equipment may be cleaned and kept in a sanitary condition.

Methods for the Microbiological Examination of Foods*

Committee on Research and Standards

THE activity of the committee during the year has been largely that of consolidating the work of previous years. Reprints of all previously developed methods were obtained from the Association and these are being revised to bring them into line with more recent developments, obtain a more uniform pattern of presenting the methods, and to eliminate duplication. Agreement is being sought among members of the committee on the establishment of incubation temperatures of 32° C., 37° C., and 55° C. as standard for food products and the elimination of odd temperatures. This is for the purpose of obtaining more uniform results and to eliminate the necessity of laboratories maintaining a number of expensive incubators. Agreement is also being sought on a simplification of the types of bacteriological media to be used. It is believed that this will assist in obtaining more uniform agreement of results between laboratories and at the same time be a saving in time and expense.

A preliminary set of methods for the Microbiological Examination of Dehydrated Fruits and Vegetables has been developed during the year and is presented for approval. The work of bringing these methods together is largely that of Matthew E. Highlands of the committee.

It was hoped that methods on Precooked Frozen Foods and on Mayonnaise and Salad Dressings could be presented at this time, but considerable new preliminary work was necessary to produce satisfactory methods. The field of Pre-cooked Frozen Foods is a new one, and Dr. B. E. Proctor is conducting research on methods for use in that field and in testing their adaptability to plant operations and routine examination. Dr. F. W. Fabian is conducting research on methods and their application in the Mayonnaise and Salad Dressing field.

TENTATIVE METHODS FOR THE MICROBIOLOGICAL EXAMINATION OF DEHYDRATED FRUITS AND VEGETABLES

Microbiological examination of dehydrated and dried fruits and vegetables has received some attention in the past but there has been little evidence of standardization with regard to methods of analyses employed. Dried fruits have had rather more attention in relation to microbiological populations and their effects on the dried product, but there appears to be at the time of writing no standardized methods of examination for microbial populations in dried fruits.

Following World War I, Prescott [1, 2] studied the microflora of some twenty commercially dehydrated fruits and vegetables, using plain agar, glucose agar, and litmus agar, and reported that counts of bacteria varied from 60 to 2,000,000 per gram of sample while

* *Report of the Committee on Standard Methods for the Microbiological Examination of Foods of the Coördinating Committee on Laboratory Methods.*

COMMITTEE ON MICROBIOLOGICAL EXAMINATION OF FOODS.

Organized *1932. Formerly under* the Food and Nutrition Section. As such the following Reports were published: *Year Books*, 1935–1936, 1937–1938, 1941–1942, *A.J.P.H.*, June, 1943; August, 1945, April, 1946. *Year Book*, 1947–1948.

mold counts varied from 20 to 600. Types of organisms encountered were nonpathogenic. Later Prescott[3] and others investigated freshly dehydrated vegetables with similar results. Risbeth[4] examining dehydrated vegetables found that the majority of surviving organisms were Gram-positive spore forming rods and cocci. A few coliform types were also encountered and various fungi and yeasts were frequently found. Potential pathogens were rare. Counts for dehydrated vegetables varied from the order of 10^3 to 10^6 per gm. of sample and the organisms appeared to occur mainly on the surface of the vegetables. He indicated that the plate count is useful as a guide to the conditions of plant sanitation. Lochhead[5] indicates that as a result of researches an acceptable limit of 50,000 bacteria per gm. can be placed on dehydrated vegetables which have been subjected to blanching during processing. The Division of Bacteriology and Dairy Research, Department of Agriculture, Dominion of Canada,[6] in their published methods for bacteriological analysis of dehydrated vegetables recommended a total viable bacterial count, a thermophilic bacterial count, and a coliform bacterial determination.

The microbiological populations of dried and dehydrated fruits differ considerably from those of dehydrated vegetables in that yeasts and molds are the predominating organisms encountered with bacteria occurring in smaller numbers, Phaff.[7] In the case of dehydrated vegetables few yeasts should be encountered but bacteria and molds occur frequently. The presence of large numbers of organisms in any of these products indicates poor plant sanitation and handling, or substandard quality of the raw products prior to processing.

From reports in the literature it would appear that microbiological examination of dehydrated fruits and vegetables should include viable plate counts for bacteria, yeasts and molds, and a direct microscopic count to establish previous sanitary history. Thermophilic bacterial count should be included when the dehydrated material is intended as an ingredient in a product that might undergo thermophilic spoilage.

In this report the products to be examined are divided into two main groups as follows:

I. Dehydrated or Dried Vegetables
   A. Leafy Vegetables
   B. Root Vegetables
II. Dehydrated or Dried Fruits

COLLECTION AND HANDLING OF SAMPLES

Sample containers should be moisture-proof screw top glass jars, and prior to use should be cleaned, rinsed in distilled water, dried, and sterilized.

Samples of dried or dehydrated vegetables and fruits should be collected, using aseptic techniques. Care must be exercised to secure a representative sample. At least a 16 oz. sample should be taken from each lot or container of product under examination. If in small packages, a representative sample should be taken from several packages. Following selection, samples should be handled in such a manner that no contamination or other changes occur prior to examination, and they should be examined as soon as possible after taking.

MAKING VIABLE MICROBIAL COUNTS

I. *Dehydrated Vegetables*
   A. *Leafy Vegetables*
      1. Aseptically weigh 10 gm. of sample into a sterile screw top pint jar and add 190 ml. of sterile water. Replace screw cap and allow to rehydrate for 2 hours at room temperature, but not to exceed 70° F.
      2. At the end of this period shake thoroughly for 2 minutes.
      3. (a) Prepare suitable dilutions from the above 1:20 dilution according to the procedures given in *Standard Methods for the Examination of Dairy Products*,[8] and pour plates for total viable yeast and mold

counts, using Difco Malt Extract Agar containing 30 gm. of agar per liter and adjusted to a pH of 3.5.

(b) Incubate at 32° C. for 5 days observing the usual practices described in *Standard Methods for the Examinatino of Dairy Products,*[8] and report the counts as numbers of yeasts or molds per gm. of dehydrated product.

(c) Pour plates for total viable bacterial counts according to *Standard Methods for the Examination of Dairy Products,*[8] using Tryptone Glucose Extract Agar.

(d) Incubate plates for 48 hours at 32° C. and report the count as numbers of bacteria per gm. of dehydrated product.

B. *Root Vegetables*

Procedures for examination of dried or dehydrated root vegetables should follow those outlined for leafy vegetables except that it is desirable to permit the original dilution to stand overnight at refrigeration temperatures (32°–36° F.) to permit the sample to rehydrate before proceeding with the shaking of the sample and preparing subsequent dilutions.

II. *Dehydrated or Dried Fruits*

1. For prunes, apricots, peaches, and dates, etc., aseptically weigh 20 pieces of fruit into a sterile screw cap jar and add 200 ml. of sterile water. For raisins, currants, etc., weigh 100 pieces of fruit into similar jars and add 200 ml. of sterile water. Allow to stand 30 minutes at room temperature.
2. Shake for 2 minutes.
3. (a) Prepare suitable dilutions according to procedures given in *Standard Methods for the Examination of Dairy Products,*[8] and pour plates for total viable yeast and mold counts, using Difco Malt Extract Agar containing 30 gm. of agar per liter and adjusted to a pH of 3.5.

(b) Incubate at 32° C. for 5 days and report the counts as numbers of yeasts or molds per gm. of dehydrated fruit.

(c) Pour plates for total viable bacterial counts, using Tryptone Glucose Extract Agar.

(d) Incubate plates for 48 hours at 32° C. and report the count as numbers of bacteria per gm. of dehydrated fruit.

MAKING DIRECT MICROSCOPIC COUNTS

In order to establish the sanitary history of the samples of dehydrated fruits or vegetables, prepare slides for direct microscopic examination according to the method outlined in the *Standard Methods for the Examination of Dairy Products.*[8]

The liquid should be taken from the jar in which the sample was rehydrated, after settling in order to avoid debris, spread on the slide, stained and examined according to the above methods. Report as microörganisms observed per gm. of dehydrated product.

Public Health Significance, Distribution and Control of Air-borne Pollens*

Engineering Section

IN October, 1947, at the Atlantic City meeting of the American Public Health Association, the Committee on Air Pollution of the Engineering Section presented its first report.[5] The substance of that report was a general review of *atmospheric* pollution and its control. Part of the report was given over to a discussion of pollen control, with a section on the current work being carried on in New York City with regard to ragweed reduction. The committee's entire report has been published in the June, 1948, issue of the *American Journal of Public Health.*

This committee, after consultation between its members, decided that a review of the subject of hay fever pollen control and a statement of pertinent information available at this time could well form the subject of this year's report.

The American Public Health Association offices had been asked for advice on this general subject. There was a considerable amount of interest among public health engineers and other public health officials as to whether an extended program in hay fever pollen control is justified.

OBJECTIVES OF THIS REVIEW

This report is prepared with these objectives in mind:

1. To determine the characteristics of pollen and the factors affecting its air-borne distribution.
2. To review the results of efforts to control hay fever pollens.
3. To provide a theoretical and actual basis for judging the likelihood of success of various pollen control methods.
4. In general, to provide a collection of present knowledge for administrative use by health officials and other individuals or agencies contemplating hay fever control programs.

PUBLIC HEALTH SIGNIFICANCE OF POLLENS

It has been stated[13] that from the standpoint of preventive medicine and public health, the illnesses caused by pollens have not received the attention they deserve. While pollinosis is not an infectious disease, nevertheless it is one which goes through epidemic periods. It is one of the few diseases for which one can predict with much precision, the time of occurrence, the period of duration, and the number of persons who will be affected in a single epidemic.

As hay fevers or pollinoses are not reportable, the number of individuals who are affected is not accurately known. Estimates of the number of persons who suffer from hay fever sometime during the year have been variously given. The U. S. Public Health Service[27] estimated that 2 to 3 per cent of the inhabitants of the area in the United States east of the Rocky Mountains where ragweed pollen is the principal cause of the disease, are affected. A survey conducted by the

* Report of the Committee.
COMMITTEE ON AIR POLLUTION.
Organized 1946. Published Report: *A J.P.H.* June, 1948

U. S. Public Health Service [18] (National Health Survey) during 1935–1936 disclosed that hay fever was 4th in prevalence in a list of chronic diseases, (14.3 cases per 1,000 persons among adults 20–64 years of age), exceeded only by (1) rheumatism and allied diseases, (2) cardiovascular-renal diseases, and (3) orthopedic impairments. Dr. Ralph V. Ellis in an article on pollinosis [13] estimates that from 2 to 4 per cent of the United States population suffer from hay fever. He reports a study based on personal histories taken at entrance to the University of Minnesota, which showed that 5 per cent of the students reported having hay fever. He points out that incidence of the disease is approximately equal among the sexes.

It is generally agreed that hay fever is not only common but has been steadily increasing from year to year. This is believed to be a real increase and not one due to better recognition or identification of the disease. R. P. Wodehouse [31] maintains that this increase is due primarily to the continuous increase of hay fever plants, given favorable environments by some of man's farming and urban land-use practices. The etiologic agent is a single living cell, pollen, and in each case, this agent releases a toxic or harmful substance which produces a characteristic effect only in such individuals as are susceptible to its action. The susceptibility is an acquired state and is termed an allergy.

Hay fever usually manifests itself as repeated sneezing and swelling, congestion and watery discharge from the nasal mucous membrane, starting relatively abruptly, and continuing over a prolonged period; the symptoms being produced whenever the individual inhales air with a sufficient concentration of certain pollens. Pollen entering the eyes produces a similar effect. Heredity plays an important part in causing individuals to be predisposed to develop hay fever at some time in their life. The disease develops at unpredictable ages, in babies as well as persons past 60. However, most persons who will develop the disease do so before the age of 30.

The mortality from hay fever is not known accurately but allergists agree that it is probably low. There is no recorded mortality from hay fever alone. However, when asthma supervenes, the mortality may be definitely increased. Dublin [7] concludes that on male risks with asthma, the mortality in the aggregate is 27.4 per cent in excess of that expected by the American Men's Table and 63.7 per cent in excess of the Basic Mortality Table. A majority of those who become susceptible to pollen, sooner or later develop asthma. Thommen [4] reports that pollen asthma occurs in about 35 per cent of all hay fever subjects in New York and vicinity, while Huber [21] reports 54 per cent for Chicago and vicinity. Ellis [13] points out that the incidence of asthma increases with the number of attacks of hay fever. Whereas the incidence of asthma is only 17 per cent among those with a history of 5 attacks or less, about two-thirds are so affected among those in whom the attacks have been repeated 25 or more seasons.

A majority of individuals suffering from pollinosis are susceptible to the excitants of 2 or more pollen groups. Ellis [13] states that without accurate information concerning atmospheric pollen pollution, it is impossible to make an accurate diagnosis of the causes of hay fever for the individual patient. Patients often react positively to skin tests with pollens to which they exhibit no clinical sensitivity. Obviously, the period of illness for the patient must coincide with the period of atmospheric pollution by the pollen which induces a skin reaction, before this has any diagnostic significance.

The amount of time lost and the losses due to reduced efficiency are not

easily estimated. However, it is easy to understand that these are very considerable. Such losses include an inability to get the proper amount of sleep, a production and aggravation of irritability and, particularly, a lack of interest in the usual activities, including the day's work. The eye symptoms may require the elimination of jobs in which the visual tasks are important.

It would appear rather conclusive from the above that the control of hay fever is easily justified as a worth while public health activity, *provided* an effective method is available which

a. Would reduce the amount of all hay fever pollens in the air below the number which would produce hay fever symptoms for all susceptible persons, over a considerable portion of the hay fever season, or
b. Would reduce the amount of all hay fever pollens to an amount which would be sufficient to prevent the disease in *most* sufferers for the duration of their symptoms, or
c. Would reduce the amount of *certain* individual pollens or groups of them to a concentration which would prevent the hay fevers of most sufferers.

As with many public health programs, it becomes an administrative decision as to whether the results to be obtained justify the effort and expenditure of funds necessary to achieve sufficient return. (1) The measurement of the seriousness of the problem, (2) the limitations involved, and (3) the level of accomplishment that could be expected in any one locality will be discussed in principle in the remainder of this report. Unfortunately, there are still considerable gaps in the information available on which such an administrative decision could be based, even if all the principles were known and were sound.

BOTANICAL CHARACTERISTICS OF POLLEN CAUSING HAY FEVER

Wodehouse in his book *Hay Fever Plants* [33] points out what makes some plants cause hay fever. He states that in order to cause hay fever, pollen must have certain characteristics. There are in summation: (a) buoyancy, (b) abundance, (c) allergenic toxicity.

If a plant is entirely entomophilous (pollinated chiefly by insects) it can be unconditionally excluded. If the plant is loosely entomophilous or is amphiphilous (pollinated both by insects and wind) it may be suspected, especially if it belongs to one of the hay fever plant families. But it is only among the truly anemophilous (pollinated chiefly by the agency of wind) that one should look for the important causes of hay fever. And by no means are all of these important, as they possess only one attribute—buoyant pollen. Most anemophilous plants produce or shed far too little pollen or the plants themselves are too scarce to be of any consequence in hay fever production.

The allergenic toxicity is of equal importance. This can be decided with considerable certainty by an actual clinical test with pollen-sensitive individuals. However, this character is found only in certain families of plants. The most important are listed by Wodehouse as follows:

Weeds and Grasses

Gramineae, the grasses
Compositae, ragweeds, mugworts, goldenrods, etc.
Chenopodiaceae, Russian thistle, saltbushes and chenopods
Amaranthaceae, pigweeds and waterhemps
Plantaginaceae, plantain
Polygonaceae, dock and rhubarb

Trees and Shrubs

Betulaceae, birches, alder and hazel
Fagaceae, beeches, oaks and chestnut
Ulmaceae, elms and hackberry
Moraceae, mulberries and paper mulberry
Juglandaceae, walnuts and hickories
Salicaceae, poplars and willows
Aceraceae, maples
Oleaceae, ashes, olive, and privet

Summing these up, Wodehouse in his article in *Natural History* [31] states: "There are other plants which contribute in small degree to the production

of hay fever, but the seven grasses, the two ragweeds and the related false ragweed and bur ragweed, the sagebrushes, mugworts and wormwoods and Russian thistle account for so nearly all of it in North America that without them hay fever could be little more than a local phenomenon of academic interest."

The "seven grasses" listed by him are:

Sweet vernal-grass
June grass
Orchard grass
Timothy
Red top
Bermuda grass
Johnson grass

The two ragweeds, of course, are the short, *Ambrosia elatior* or *Ambrosia artemisiifolia,* and the giant *Ambrosia trifida.*

Three hay fever seasons are distinguishable in the northeastern portion of the United States. They are as follows:

Early-spring hay fever—Caused by pollens discharged from elms, oaks, birches, and poplars which flower early while still leafless. In the South, the cause is pollen from pecan trees; in the cities of the Middle West and Rocky Mountain states, it is boxelder. Around Christmas time, the offender in Texas and Mexico is mountain cedar.

Early-summer hay fever—Sometimes known as the "rose cold." It is more prevalent than early spring hay fever. The cause is pollen from grasses (first five listed above). In the South and West, Bermuda and Johnson grasses are important causes.

Autumn hay fever—This is the one which involves over 80 per cent of all hay fever sufferers. The principal causes in the area east of the Rocky Mountains are the short and giant ragweeds. False ragweed and cocklebur are also involved. Sagebrushes, mugworts, and wormwoods are the offenders in the West.

Ragweeds owe their great abundance to their extraordinary ability to take possession of freshly disturbed or denuded soil and to the longevity of their seeds. Seeds of ragweed have been shown to remain viable after 40 years of burial in sand. Ragweeds are found profuse in vacant lots, waste places, dumps, roadside ditches, and on neglected farm land. The ragweed is an annual plant. It is spoken of by botanists as a "pioneer" plant. It will persist so long as the soil is disturbed but it cannot stand competition. In fact it normally flourishes only a few seasons if left alone and the late-weeds or intermediate group of plants take over the soil which the ragweeds have prepared for them. They, being winter-living plants, will have a good root system developed by spring so as to provide too much competition for the ragweeds.

Considerably later, what is called climax vegetation (association of plants best suited to the climate of the particular locality) will take over from the late-weeds or intermediate stage.

In the urban areas, ragweeds may be highly abundant, especially in the partially settled districts around towns and cities.

Wodehouse points out that the Indians were not bothered by ragweed hay fever, as only along streams and rivers where the undercutting of banks by the water disturbed the soil, could ragweed plants find suitable conditions for their growth. He theorizes that this may explain the huge amounts of pollen discharged by ragweeds as a device developed in an evolutionary way to provide a means of transfer of pollen between the widely scattered plants of the primeval forests.

Somewhat different is the cause of the increase of sagebrushes, mugworts, and wormwoods. These are bad-tasting plants, avoided by grazing animals as long as they can obtain other food, with the result that excessive grazing will remove the other plants leaving these weeds in possession.

Pollen granules are exceedingly minute, although they vary greatly in size, shape, and structure for different species of plants. Their size ranges from about

15 to 45 microns in diameter, although extreme cases may be found of pollens much larger or smaller than this. Some pollens are spherical or nearly so; others have very different shapes. Most have a sculptured outer coating, furrowed, or with pores, spines, and ridges in great variety; some have wings, bladders, or other appendages to assist their flight. Almost all are hygroscopic and individual grains vary considerably in size and weight according to their moisture content. The outer coating is highly resistant. Under favorable conditions it will last for thousands of years. The study of fossil pollens preserved in peat bogs gives considerable information as to climate conditions and periods of the past.

A pollen grain remains alive so long as it retains its ability to fertilize the plant egg cell. This may vary from a few hours to several months. However, the fertilizing ability has apparently nothing to do with the reaction of pollen on sensitive persons. If pollens are kept dry they retain their power to cause hay fever symptoms indefinitely. Pollen that is 20 or more years old is often found to be almost as active as ever in its allergenic properties.

The factors[28] which determine the stability of the allergenic component of a pollen are not fully established. However, it has been shown that storage without adequate drying speeds the rate of denaturation, and more particularly so if stored at relatively warm temperature. Extrinsic moisture (humidity, dew or rain) provides favorable conditions for fermentation and souring of the pollen due to the activity of contaminating microörganisms. Intrinsic moisture is necessary for enzymatic activity within the grain. These denaturing activities can be slowed, if not arrested, by storage at temperatures below freezing or by removal of the moisture to below the critical level for enzyme and microörganism activity.

DISCHARGE OF POLLEN

The amount of pollen discharged to the atmosphere in any given area will depend on a number of factors[3]:

1. Pollen output of the individual plant flower—This is a function of the species and size of plant. Erdtman[14] reports some counts of pollen granules from individual flowers of trees, ranging from 10,000 to 1,800,000 grains.

2. The size of the plant—More pollen will be discharged from larger plants. Numbers of pollen from certain trees could be from 2,000 to 12,500 millions of grains (whole tree).

3. Abundance of the plants—Obviously the greater the number of plants, the greater the total amount of pollen discharged.

4. Velocity of wind and time of day when velocity of wind is great—Pollination is heaviest in the early morning hours, which will produce more pollen discharge if the wind velocity is high at this time.

5. Sunshine—The amount of sunshine determines to a considerable extent the amount of pollen liberated from the pollen pods.

6. Relation of the date to the pollination period—As the pollination period continues, more plants come into pollination, more flowers open, etc.

7. Variation in temperature—This appears to have little effect on the transportation of pollens, other than in its relation to winds. However, low temperatures may delay and high temperatures hasten the growth and blossoming of plants. Early high temperatures may produce an earlier pollination season, particularly with tree and grass pollens. It does not affect the weed pollens nearly so much as they mature late in the summer. Unseasonably cool night temperatures may reduce the discharge of pollen, but when warmer weather returns, pollen production is resumed.

Frost is of importance in terminating the ragweed season in some northern states. However, in most of the ragweed areas, the pollination season is over several weeks before frost.

Pollination may be thought of as a tremendously wasteful process. So much pollen is given off by such trees as pines, firs, hemlocks, and spruces as to be seen floating like a cloud above the forests. Wind pollinated plants are characterized by flowers of simple structure. Such flowers are not showy, do not produce nectar, are not scented, and are of little or no interest to insects. The pollen produced may be enormously

more than that from insect-pollinated plants, though this is not always true. Such pollen is dry, light, and powdery.

DISSEMINATION OF POLLEN

Although exact information concerning the extent of dissemination or transportation by wind is governed by so many factors as to be relatively impossible of exact analysis, there is considerable evidence to show that pollens may be transported for very great distances.

Erdtman [14] quotes several studies which have shown large numbers of pollen grains caught on slides on ships from 20 to 30 miles off shore. He also presents many examples of small numbers of pollen grains being found hundreds of miles from their probable source. He records a journey across the Atlantic Ocean in which he exposed slides and caught pollen grains in mid-ocean and throughout the trip, some of which had to travel at least 600 miles.

Similar studies [22] carried out in airplanes, show that local pollens are found up to at least 4,000 ft. above the earth. Other pollens blown from considerable distances were found up to 5,000 feet.

Oren C. Durham,[10] one of the leading allergists in the United States, declares: "Even the absence of ragweeds in a given region cannot be accepted as proof of the virtues of that region as an effective refuge from ragweed pollen, for we know that pollen may be blown in toxic amounts for hundreds of miles." Balyeat [3] is more conservative in his statement: "The actual location of a majority of plants is not such an important factor if they are within range of 3 or 4 miles of a city, for from this distance the pollen will be brought in by means of the wind. This will hold true for all plants with the exception of a few whose pollen is very heavy."

Without question, the farther from the source of pollen one removes oneself, the greater the reduction of pollen numbers is likely to be, other things being equal. The reduction of pollen numbers in the atmosphere in general must vary inversely as at least the square of the distance from the point of production and probably is reduced at a much faster rate. Much of the pollen discharged falls to the ground near the plant. Rising air currents and strong winds moving long distances may void such a mathematical treatment, by carrying pollen for long distances.

Two meteorological conditions may seriously affect the amount of pollen remaining in the air. These are:

1. Precipitation — The rainfall during the growing season will determine to a considerable degree, the extent of growth and the number of plants which in turn will affect the amount of pollen produced.

During the pollination season, rainfall may tend to wash pollens out of the air but not necessarily as much as might be anticipated. Sustained rains are required. Balyeat [3] correlated air pollen counts with rainfall, sunshine, and wind velocity in three large cities of the Midwest states. He states that a slow rain over a period of 2–3 days accompanied by cloudy weather will practically clear the air of pollen.

2(a) The velocity of wind—This determines to a major degree how much pollen gets into the air, how far it will be carried, and the amount coming in contact with the hay fever sufferer. Patients complain of symptoms much more bitterly on windy days. Other factors being equal, the number of pollen grains found on a slide will be in direct ratio to the wind velocity.

2(b) The direction of the wind—This is of great importance in determining the concentration of pollen in the air. If it blows from an area where hay fever plants are abundant, the amount may be high. Cities near oceans or large lakes which are favored by breezes off these bodies of water during much of the time will have lower pollen concentrations than other cities, not so favored.

MEASUREMENT OF POLLENS IN THE ATMOSPHERE

Any method of quantitative determination of pollen content of air must take into consideration the considerable pat-

tern of variation which will be encountered.

Pollen concentrations will vary from place to place and from hour to hour in a given location. The factors governing the discharge of pollen and its dissemination by wind are so many and so variable that the errors of sampling can easily produce seriously misleading results if they are not taken into consideration.

Methods of measuring pollen in air fall into two general groups: volumetric methods and so-called gravity methods. Wodehouse[33] describes the following volumetric methods:

1. Erdtman Air Filtration Method—A small vacuum cleaner with its filter bag replaced by a plaited filter paper supported on a metal frame. The device has a means of measuring the volume of the filtered air.

2. Wells Air Centrifuge—This consists essentially of two concave discs set face to face. Air drawn into the lens-shaped cavity between the discs is projected by the rapid whirling of the lower disc directly onto a celluloid foil supported by a collar surrounding the slit. The amount of air sampled by the instrument in a given time interval can be readily determined.

3. Continuous pollen measurements[19] have been made by an apparatus with a clock-work mechanism which moves a slide across a jet of metered air which impinges upon it through a slit. The fluctuations in pollen density are recorded and can be measured by microscopic counting.

Various gravity methods have been described in the literature. In general, they are variations of methods of exposing a petrolatum—or glycerine-jelly coated miscroscope slide, held horizontally, with a sheltering device to protect it from rain and from the fall of large particles of dust and soot. A committee of the American Academy of Allergy has proposed the standardization of pollen sampling techniques and has published a preliminary report.[12] The details of the proposed standard technique are given in full in Appendix B of this report.

The counting procedure in all cases is by means of a microscope, usually at a magnification of 100 times. In addition to counting the pollen grains, an attempt is also made to identify the species or family of the plant from which the pollen originated.

Training and experience is of major assistance in making this identification. Some help may be obtained from available books on the subject, such as Wodehouse's *Pollen Grains*[30] or his article "Atmospheric Pollen."[32] He advises that final identification be made by actual comparison with known material. For this purpose, a reference collection of mounted specimens of pollen is necessary. Methods of collecting and preserving herbarium specimens are given by Bailey[1] and by Swingle.[26] Wodehouse describes the method of collecting and mounting the pollen.[33]

It is only rarely possible to tell the exact species, but it is generally possible to determine the genus and, almost always, the family. The species can usually be judged with only minor errors, by a knowledge of which plants are flowering at the time the pollen is caught.

None of the gravity methods provide a reliable index to the absolute amount of pollen in the air nor can they be expected to show a high degree of correlation with the volumetric methods. Some authors[23] have assumed that the number of pollen grains falling on a unit area of a slide in a given time interval depends upon only two factors, the abundance of pollen grains in the air and their rate of fall. By use of Stokes's law, or by direct measurement more recently,[11] they have determined the velocity of fall. This permits them to make a calculation of the number of pollen grains per unit of air volume (usually expressed as number per cubic yard) from the number of pollen grains found on a unit of area of the slide.

In addition to the questionableness of the assumptions, the original paper

setting up a table of velocities of fall contained a serious error in its calculations,* which went unchallenged for many years during which time the table was used as a basis for volumetric calculations in many published pollen surveys.

However, in addition, other factors undoubtedly enter into the relation between gravity and volumetric measurements to confound the person attempting to make such transfer calculations. These include:

1. The shape and sculpturing of the pollen grains.
2. The variability of the specific gravity of the grains, of the air temperature and of the humidity.
3. The velocity of the wind and the direction in which it impinges on the coated microscope slide.

It is generally accepted now[6, 12] that reports of gravity samples should include a record of the amount of pollen per unit of area of the exposed slide whether volumetric data are calculated or not.

Some effort has been made to determine the threshold concentration of pollens, i.e., the number per unit volume of air required to produce symptoms of pollinosis.

Feinberg and Steinberg,[15] in correlating their pollen counts with hay fever symptoms, using Scheppegrell's formula, found that their counts indicated that 25 grains of ragweed pollen per cu. yd. was sufficient to produce symptoms. However if a correction is made for Scheppegrell's error and an allowance for the spicules on the ragweed pollen grains, the number should be 196 grains per cu. yd. or about 3,920 inhaled per day (assuming that the individual engaged in average activity inhales about 20 cu. yd. of air per day).

A concentration less than this, states Durham[9] "can hardly be regarded as a severe hazard for the average ragweed-sensitive person."

Gottleib and Urbach[17] state more recently on this question, "There is no present method of determining the clinically significant concentration of pollen." They point out that individuals vary greatly in degree of sensitivity.

A considerable amount of information regarding the amount of pollen to be expected in the atmosphere of any particular locality can be gathered:

1. By securing the information given in the very numerous published surveys of hay fever plants. Most areas are covered by such published material, particularly as to the more common hay fever producing plants. Such surveys usually give the names of the plants, the time of flowering and some indication of the amounts of each different kind of pollen which can be expected in the air. Supplementary information can usually be obtained from the curator of local or nearby botanical collections.

2. By a field survey. In order to bring the published information up to date, to apply it to a particular locality or to test its reliability, it is usually desirable to make a field survey of possible hay fever plants. Such surveys need to be sufficiently comprehensive so that representativeness is assured. This survey also provides an opportunity of collecting samples of various pollens for purposes of identification of air-borne samples. Field surveys should be closely coördinated with air sampling.

There has now been accumulated a large number of published surveys, which give the distribution and pollination times of hay fever producing plants in various localities and regions of the United States.

Wodehouse lists a large number of them in his book, *Hayfever Plants*.[33] Gottlieb and Urbach[16] have also listed a large bibliography, classifying the areas covered, by individual states. These latter authors[17] have discussed the deficiencies of some field surveys, pointing out that plants should be identified by scientific rather than common names to avoid confusion; pollination dates should be given exactly rather than

* The diameter rather than the radius of the pollen grains was used in the Stokes's law substitutions

roughly by months; and that surveys need to be carefully done, particularly as to representativeness. Otherwise errors of sampling will invalidate the results.

One of the outstanding surveys of national scope has been that pursued by Durham.[8] With commercial assistance and with the coöperation of the weather bureaus of the United States, Canada, and Mexico, he has organized extensive studies of atmospheric pollen counts in many cities of various parts of North America. These studies were limited to late summer and fall seasons. Two tables of pollen counts in these various cities as compiled from those studies are given in Appendixes C and D at the end of this report. One illustrates the relation of ragweed pollen counts to airborne concentrations of other pollens. The other gives data on variation, seasonal length, and total ragweed counts. Both tables are given in count of pollen per 1.8 sq. cm. The samples were collected by various observers using the gravity method, and were counted by Durham.

Dr. Harry S. Bernton,[8] in discussing a similar tabulation of pollen counts, points out that because some cities have more pollen than others at a given time, does not signify that residents of those cities suffer in proportion. He brought out that there is a minimal requirement of pollen for intoxication and all in excess of this does not influence the disease proportionately.

It has become customary in many large cities for local newspapers to publish daily pollen counts, made by private laboratories or allergists. With standardization of counting and greater interest in the subject, health officials may well give consideration to promoting an official daily pollen count. This could be based on representative sampling made either by the local weather bureau, by the local public health laboratory, or by some other suitable official agency. Such a record will be very valuable in measuring the long-term effect of a pollen control program, in addition to its obvious diagnostic aid to the physician.

CONTROL OF AIR-BORNE POLLENS

The prevention or control of pollinosis falls into several categories:

I. Action by the individual to reduce severity of symptoms—

a. Avoidance of undue exposure to pollens by allergic or potentially-allergic individuals
b. Avoidance of foods which aggravate the sufferer's symptoms.
c. Avoiding excessive physical activity, fumes, dusts, and chilling of the body.

II. Preventive or immunizing treatment of allergic individuals—This includes sensitivity tests to determine the pollen or pollens which cause the hay fever and the correlation of beginning and duration of symptoms with atmospheric concentrations of pollens. This may be followed by:

a. Pre-seasonal treatment by gradually increasing parenteral injections of specific pollen extract.
b. Similar treatment given during the hay fever season.
c. Injections given at regular intervals throughout the year.

Pollen extract treatments have been given for over 35 years and the outlook has changed from one of "utter hopelessness to optimism."[9] The recent development of group antigens is providing for highly successful treatment and greatly simplified diagnosis and treatment.[13]

III. "Hay fever-free areas"—Many sufferers for years have been seeking hay fever relief by migration to so-called hay fever resorts. As the "Chamber of Commerce" influence and commercial interests are closely tied into the promotion of such resorts, it may be said that their efficacy is hardly ever as good as claimed. Besides this, even if relief is

found at a particular resort, the hay fever returns, when the allergic person is compelled to stay at home. Running away from hay fever is also time consuming and may be expensive. Psychologically it is not good. Few of us relish a vacation if the time and the place are selected in advance for us.

IV. Removal of pollens from the air—Personal respirators and various types of filter-masks designed to remove pollen from the air breathed, have also been tried with little success. They are very little help to the highly sensitive individual or the one affected by other factors in addition to pollen—such as cold air or certain foods. Those persons with asthma usually are not helped in this way. On the whole, none of these devices can be effective as the mesh of the filter cannot be made fine enough to keep out pollen without producing a device which is unwieldy and uncomfortable. Also many persons would need goggles in addition because eye symptoms of hay fever are caused by pollen entering the eyes directly.

One of the simplest ways to avoid much pollen is to remain indoors. In rooms where air is comparatively still, pollen content of the air is much lower than on the outside. However, if windows or doors are opened while a breeze is blowing, or if a fan is used to circulate the air, the pollen count will be near that of the exterior air.

Filters to remove pollen from indoor air are very feasible and effective. In general, air filters, precipitators, or washers which are effective against the dust will also protect against pollens.[25] Hay fever sufferers find that considerable temporary relief can be obtained by providing for filtration of air for their bedrooms. They find similar relief in "air-conditioned" buildings if the air-conditioning includes effective dust removal.

Unfortunately, the symptoms of hay fever reoccur when the allergic person returns to a pollen-laden atmosphere, and there are few persons who can remain in an air-conditioned atmosphere for any considerable portion of the hay fever season.

V. Theoretically, by preventing the discharge of pollen into the air, its effects could be avoided—Elimination of the plants which produce the offending pollens would accomplish this. Obviously, this is impractical for the tree pollens, and it is highly unlikely that any effective effort along this line can be carried out on the grasses, inasmuch as they form some of our most important agricultural crops.

The idea of elimination of the weed-produced pollen by destroying the weed plants has enjoyed a much wider support and it is undergoing a revival of interest now. Its appeal is primarily because most hay fevers are caused by weeds and also because weeds are otherwise highly objectionable.

Weeds have been defined as undesirable plants or just "plants in the wrong place." Weeds in the rural areas are likely to be costly hazards to crops and in some respects to cattle, as well as unsightly. In urban areas, they produce traffic hazards, fire hazards, and tell a tale of neglect and disregard of neatness and good municipal housekeeping.

In the past, municipal authorities have made heroic efforts, through legislation, enforcement, education, and direct weed removal service to suppress weed growth. These have taken the following lines:

1. Cutting of weeds before they reached a certain height.
2. Grubbing out or pulling weeds.

Attempts to enforce city laws requiring the property owner to cut or pull weeds have been very costly and relatively ineffective. Property owners could not be located and many could not be induced to do the work in time to prevent pollination or reseeding. Where the

work was done by the city and charged to the property owner, costly and delay-involving notification and hearing procedures are involved. Many cities still hold huge numbers of special tax liens for weed cutting which will never be collected because the property value now is less than the general taxes also due against it.

Centrally directed or municipal services of weed cutting or grubbing have been more successful in keeping weeds under control and to some extent in preventing reseeding, but have been very costly, need to be repeated frequently, and do not prevent pollination. The weeds grow back, pollinate and produce seeds in a few weeks' time. Also, where the soil is disturbed, the botanical progression of normal replacement of pioneer weeds, such as ragweed, by late-weeds is prevented.

Wodehouse [31] has advocated the planting of disturbed or denuded areas and intensive cultivation of all areas to prevent the ragweeds from taking over. He points out that city parks, properly kept gardens, well managed farms, and carefully planted roadside ditches and highway shoulders do not support hay fever weeds. As a long-term program, such activity will have many beneficial effects besides reducing the opportunities for ragweed growth.

Recently, there has been a revival of weed elimination enthusiasm. The cause has been the announcement in 1944 of a plant growth-regulating substance or hormone for use as an herbicide. At 10 p.p.m., more or less, plant hormones produce beneficial results. When this is increased to between 100 and 1,000 p.p.m., the new plant hormone, 2, 4-Dichlorophenoxyacetic acid (known more familiarly as 2, 4-D) stimulates abnormal growth which finally results in death of the plant. Under favorable conditions, 2, 4-D applied to foliage in the latter concentrations causes death of the entire deep root system. It is non-corrosive, non-irritating to the skin, non-explosive and apparently non-toxic to animals and man.

The action of 2, 4-D is highly selective. It attacks most broadleaf plants but there are exceptions. It does not affect most grasses. It appears to be most effective on young plants in periods of rapid growth; it acts slowly, requiring a month to produce killing action. It appears to be most effective when applied to plants growing in moist soil. The action progresses more rapidly in sun than in shade and its effectiveness is reduced when applied within 4 hours of a rain.

This is some of the knowledge gained of its general action.[20] Specifically, it has been investigated as to its effect on ragweed and related plants.[24]

Water sprays of 2, 4-D at 1,000 p.p.m. at sufficiently early stages of flower development were shown to be effective in preventing pollen shedding by ragweeds. If applied when the majority of plants had small racemes (flower stalks), by the 14th day, none of the involucres (covering of unexpanded flowers) had opened and no further flower development occurred. The plants, of course, did not produce seeds. By the 28th day, the tops of one-half of the smaller plants were dead and larger plants were dying back from the tips. Even when spraying was done as involucres were starting to open, no pollen was shed. Later spraying reduced pollen shedding but did not prevent it.

A number of city officials have experimented with the use of this compound as a weed killer. Many cities have started to use the material in more extensive programs. New York City organized an extensive ragweed control program starting in 1946, using 2, 4-D spraying. Details of this development can be found in the publication by Weinstein and Fletcher [29] which appeared in the *American Journal of Pub-*

lic Health and in the special report, prepared by Pincus, which is a part of Appendix A of this report.

Results of the New York City program as reported are: little or no new growth of ragweed in 1947 on areas sprayed in 1946, encouragement of growth of late-weeds and grasses where ragweed grew before, and possibly some effect on atmospheric ragweed pollen counts during the 1946 season. These were reported as "unusually low" that year. It is hoped that additional quantitative data on results will be forthcoming as this program and others continue.

LIKELIHOOD OF SUCCESS OF CONTROL PROGRAMS

There appears to be little doubt that hay fever sufferers are helped by the destruction or removal of hay fever plants within a few city blocks or a few hundred feet of them.

Up to this time, it has not been conclusively demonstrated that weed cutting or weed pulling, or chemical treatment to kill weeds, even if organized on a large scale, will lower appreciably the amount of pollen in the atmosphere of American cities. However, there now seems to be considerable evidence and good reason to believe that, under favorable geographical or meteorological conditions found in many communities, a well organized ragweed control program, using the herbicide 2, 4-D in addition to other measures such as seeding areas with competitive plants, will produce a large reduction of air-borne ragweed pollen, at a reasonable cost.

Such efforts are likely to be more successful where (1) the prevailing wind direction in the community is from areas relatively free of ragweed plants, or (2) the area that can be organized and controlled successfully is large. Just how large the control area must be, appears impossible to determine from presently available data. As more control programs are carried out along with atmospheric pollen counts, more data in this regard will become usable. It would appear that one need not be hopelessly pessimistic as to results, even though one[9] of the authorities in the field has declared as late as 1936, "The complete removal of every ragweed within the area of even our largest cities for a whole season could not measurably reduce the pollen contamination of the air in the business or residence portions of the city." The fact that more hay fever cases are found in suburban areas than in the central portions of the large cities,[33] and the definite evidence of considerable and steady reduction of pollen concentrations in air the farther one travels from its source would assure increasing reduction of pollen counts at the center, as the area of comparative freedom from ragweed is ever expanded.

Preliminary evidence now at hand indicates that the beneficial results of weed control, other than potential pollen reduction, will easily justify the effort and cost of centrally organized 2, 4-D spray programs, at least in the larger metropolitan centers. Any benefits accrued toward reducing the severity and prevalence of hay fever cases will thus be added gain, should they materialize. If the community is surrounded by areas of considerable ragweed, or if a prevailing wind carries ragweed into the area, no presently available control methods can be expected to bring about a reduction of air-borne ragweed pollens to concentrations below clinically significant amounts, except on days of low wind velocity or of winds of favorable direction.

In the special cases, where cities have large amounts of hay fever plants, while the surrounding area is relatively free of them, or where the prevailing winds are from such areas, the organized control of such plants by chemical treatment would seem to be very beneficial and, therefore, advisable.

In the rural areas where efforts over

large areas are much more difficult to organize, it appears that little success can be expected through the measures recently made available for air-borne pollen control. Probably this will be so until educational means have brought the advantages of and have motivated a high proportion of persons in such areas to carry on individual weed control.

ACKNOWLEDGMENT — Full credit for the preparation of this report belongs to John Buxell of this committee, who prepared the original text which has been reviewed and approved by the committee.

The assistance of Professor A. O. Dahl of the Botany Department, University of Minnesota, in guiding the preliminary consideration of this subject through its many ramifications is gratefully acknowledged.

Appendix B

Pollen Counting

From the Preliminary Report of the National Pollen Survey Committee of the American Academy of Allergy on Proposed Standardization of Pollen Counting Techniques. J. Allergy 17:178–180 (May), 1946, by O. C. Durham, J. H. Black, J. Glaser, and M. Walzer.

1. *Essential equipment:*—

Standard sampling device.

Compound microscope (preferably binocular) with mechanical stage (preferably with graduated scales and verniers).

Glass slides, 25x75 mm. (1x3 inches), with frosted ends which may be marked with pencil thus rendering gummed labels unnecessary.

Cover glasses, 22x22 mm

Wooden slide boxes with covers, large size (25 slides) for storing slides and small size (3 slides) for carrying slides to and from laboratory and exposure site.

Soft petrolatum jelly: 75% U.S P. petrolatum, 25% U.S.P. mineral oil.

Dissecting needle.

Calberla's solution made up of 5 ml. of glycerin, 10 ml. of 95% alcohol, 15 ml. of distilled water and 2 drops of saturated aqueous solution of fuchsin. (Small tablets of basic fuchsin are prepared by Burroughs-Wellcome and Co.)

2. *Place and Time of Exposure*—The ideal location for the sampling apparatus is the center of an unobstructed roof of a tall, flat top building near the geographic center of a given community. The building chosen should not be immediately flanked by taller structures. If the roof is equipped with a parapet the top of the exposure apparatus should be 30 inches above the parapet. When for special reasons, sampling is carried on in an unusual location, a full description of the site and surroundings should be furnished. Porches and window ledges are not satisfactory sites for pollen sampling.

Slides should be exposed for periods of 24 hours, starting preferably in the morning at the same hour each day.

3. *Sampling Device*—The sampling apparatus approved and recommended as a standard by this committee, has been described and pictured in the *Journal of Allergy*, March, 1946, pages 80 and 81. Essentially it consists of two 9 inch, heavy polished, stainless steel disks set horizontally 3 inches apart and held with 3 struts. One inch above the center of the lower plane is a slide holder into which the slide fits snugly. The supporting rod of the apparatus, 30 inches long, rises from a tripod base equipped with holes so that it may be screwed to a solid platform. This apparatus may be ordered from Wilkens-Anderson Company, 111 North Canal Street, Chicago 6, Ill. (price $16.00), or it may be made according to the specification of the committee.

4. *Identification Technique*—Slides should be prepared with a very thin film of petrolatum jelly (rubbed out—not flowed on with heat). Preparation of slides should be carried out in a room free from air currents and dust particles.

Examination of slides and identification of allergenic particles may be carried out most effectively by staining with Calberla's solution. The larger dirt particles, soot and sand, should first be removed with a dissecting needle with the aid of a hand lens. A few drops of the stain are then placed directly on the slide. The amount used should be just sufficient to fill the space between the irregular oiled surface of the slide and the cover slip and will vary according to the quantity of debris on the slide. If the cover glass actually floats free, the excess stain may be removed with a blotter. The slide may usually be examined within 3 to 5 minutes after application of stain.

Identification and counting may be carried on without stain. Even when stain is used, only about half of the slide surface will be disturbed, leaving the remainder for observation of unstained granules.

The glycerin jelly method of slide preparation and counting as described by Wodehouse may be followed if preferred.

5. *Counting and Computation of Results*—For the sake of uniformity, it is advisable that counts be computed and recorded on the basis of the number of pollen grains (or spores) of each type or species found on 1 sq. cm. of

slide area. From this figure one may, if he so desires, estimate the pollen content per cubic yard of air by the use of conversion factors such as have been recommended by Durham and are now being studied by this Committee. For present purposes, however, a desirable degree of uniformity will be achieved by reporting all counts on the basis of 1 sq. cm. of slide area. Whether the 1 sq. cm. figures are supplemented by cubic yard estimates is optional with each observer.

For routine counting, low power should be used—usually a 10x objective with a 10x or 15x eyepiece. If no cover glass is used, a count is made of all pollen granules encountered in crossing the entire width of the slide (1 inch or 25 mm.). The slide is then shifted laterally and another complete crossing is made. This is repeated until 4 or more trips have been made.

The area covered on one trip across a slide depends on the actual width of the low-power field afforded by the optical combination which is being used. The width of field may be determined by reading the setting of the stage, shifting a given particle on the slide all the way from one side of the field to the other and reading again. The shift will amount to 1 mm., more or less. A number of trials should be made and the results should be averaged. If the field happens to be exactly 1 mm. then each trip across the slide will cover 25 sq. mm. Four trips will cover 1 sq. cm. If the cover-glass technique is used, the count is made across the width of the cover glass (22 mm.). If the optical field width is exactly 1 mm. each trip across the cover glass will cover 22 sq. mm. and 5 such counts will cover 110 sq. mm. or 1.1 sq. cm. From this figure, the count for the standard unit of 1 sq. cm. may be readily calculated. In the cover-glass technique, the whole area (4.84 sq. cm.) under the cover may be counted. Dividing by 4.84 gives the average number of pollen granules per sq. cm.

When there is little pollen in the air, the accuracy of the counts may be increased by counting several square cm. areas and reducing the total to the average per sq. cm.

When replacing shelters previously employed with the new standard instrument, workers are advised to run parallel counts using both shelters for one season in order to determine the equivalent values of the two instruments. With this information, one may convert readings taken in previous years to their equivalents with the new shelter. In this way, the value of accumulated data obtained by counts in previous years may be preserved.

Municipal Public Health Engineering*

Engineering Section

MUNICIPAL public health engineers need a combination of technical engineering skill and administrative ability. The technical functions are broad in scope and may cover practically all aspects of sanitation programs. In the field of sanitary engineering, private water supplies and sewage disposal installations are usually a direct responsibility. In a large number of jurisdictions the state has delegated certain responsibilities for control of public water supplies, sewerage and sewage disposal to local health officers whose staffs include public health engineers. Such delegation may include preliminary review of plans, desirable because of municipal public health engineers' knowledge of local conditions.

In coöperation with the state, supervision of chlorination, bacteriological sampling of water supplies, and control of cross-connections are local functions. Regulation and promotion of sanitary land-fills and improved general municipal waste collection and disposal directly affect rodent and insect control programs and are important responsibilities of local public health engineers.

Municipal public health engineers are directly concerned with the engineering aspects of design and installation of milk and food equipment. Since most sanitary control is based on engineering principles they must have broad technical interests.

Much basic information in these technical fields is already available. The research programs of the U. S. Public Health Service, the universities, and others are constantly adding to this knowledge. The National Sanitation Foundation program of research, combined with providing means for public health and industry to meet and arrive at mutually agreeable recommendations, is stimulating this important work.

In the field of sanitation administrative practice similar knowledge is not available. The committee reported last year on the work of its "other entity as the committee on Engineering Administrative Practice of the Conference of Municipal Public Health Engineers." It was stated that some of the fundamental administrative questions cannot be answered until comprehensive full-time studies are completed.

Among those fundamental questions are:

1. What should be the educational qualifications for sanitarians in local departments?
2. What specially trained technician services should be available to the administrator of the sanitation program?
3. What functions should be included in a well rounded health department sanitation program?
4. Under what circumstances should inspections and investigations be made?
5. How frequently should routine inspections be made in food, housing, milk, rodent control, and other programs?

Analysis of these and related factors will lead to fundamental criteria for determining the number and type of personnel needed for an adequate sanitation program.

A foundation is being laid for obtain-

---

* Report of the Chairman.

COMMITTEE ON MUNICIPAL PUBLIC HEALTH ENGINEERING.
Organized 1933. Published Reports: *Year Books* 1934–1935, 1935–1936, 1938–1939, 1940–1941. *A.J.P.H.*, July, 1947. *Year Books*, 1947–1948.

ing answers to many of these questions by the work of William T. Ingram, Director of the Engineering Section Project. "The project proposed the exploration of problems related to sanitary and public health engineering with a view toward:

"1. The provision of adequate numbers of sanitation personnel to meet the demands of good sanitation service.
"2. The utilization of engineers and other sanitation personnel in positions of responsibility more useful to the health officer.
"3. The development of sanitary engineering and public health engineering as a professional career worthy of consideration by young men now acquiring college and university training.
"4. The stimulation of expanded undergraduate and graduate training programs needed to prepare the student for his professional rôle in sanitation services.
"5. The improvement and broadening of sanitation services to insure adequate consideration of state and community requirements for a safe potable water supply; a safe and sanitary means of treatment and disposal of sewage, garbage, refuse, and industrial waste; a food and milk supply meeting standards of sanitation; a satisfactory living, working and recreational environment including housing, industrial sanitation, community air hygiene, swimming pool sanitation and other activities necessary to the promotion of the health, welfare, safety, and comfort of the individual."

One of the several accomplishments of the project is aimed at filling an important gap in our administrative knowledge by "field trials and assistance in publication and distribution of a *Sanitation Evaluation Schedule* for experimental use in the study and appraisal of community sanitation programs. (More than 800 copies of the schedule have been distributed to universities and state and local health departments.)"

The committee strongly urges that every effort be made to continue the Engineering Section Project.

In analyzing the administrative responsibilities of the municipal public health engineer the committee recognizes certain fundamental relationships. The program must be an integral part of the entire local health program. In those fields where the state has legal responsibilities the local policies must conform to those of the state. By coöperative teamwork mutual confidences develop to promote those harmonious relationships essential to successful programs.

The Engineering Section provides the important link between municipal public health engineers, health officers, state sanitation administrators and educators in the field of sanitation. Again, teamwork must be continued and expanded.

The Association's Committee on Administrative Practice, through its reports and recommendations, plays an important rôle in determining local administrative policies. The Engineering Section should have available sufficient data to assist and participate in developing formulae for sanitation administration.

Efficient administrators must decide which jobs require special knowledge and training. When a program requires the technical services of veterinarians, entomologists, biologists, food technologists, and other specialists, the public health engineering administrator must recognize the need and seek to supply those services.

Vitally needed for efficient administration is a basic method for determining the required or desirable members and types of sanitation personnel. It is urged that until such figures are available the Association refrain from recommending numbers of sanitation personnel per unit of population. Actual work measurements in 9 urban and semi-rural districts with from 70,000 to 300,000 population showed a variation of 300 per cent in district sanitarians required per unit of population.

The study indicated an overall sanitation personnel requirement of one per 6,500 population. This marked variation from other published figures such as one sanitation worker per 20,000 or 25,000 indicates the urgency of work load studies.

Health officers as well as municipal public health engineers are frequent targets of public criticism because of inadequate sanitation programs. Disgraceful housing conditions, filthy restaurants, hordes of rats, and excessive numbers of citizen complaints are largely due to grossly inadequate numbers of sanitation employees.

Another important factor is an efficient administrative program. The Committee on Administrative Practice of the Conference of Municipal Public Health Engineers has recognized the need for administrative studies. Six subcommittee reports were presented at the annual meeting covering the administrative procedures for regulating or handling:

Circuses, Carnivals and Tent Shows
Construction of Private Sewage Disposal Systems
Cross-Connections
Nuisance Complaints
Construction of New Bakeries
Adult Convalescent, Nursing and Rest Homes

Included were relationships with other local departments, procedures for reducing inconvenience to the applicants, and methods for generally improving efficiency.

In view of the interest shown and the agreed need, this type of study will be continued and expanded. A research project has been approved by the Research Grants Division of the U. S. Public Health Service to furnish answers to most of these problems. This will be done under the Association's Engineering Section Project.

Recognizing the need for continued improvement in the administration and execution of local sanitation responsibilities the committee recommends:

1. Adequate training and recruitment of sanitation personnel should be stimulated by supporting such programs as:
   a. The Engineering Section Project
   b. The training programs of the U. S. Public Health Service and the Kellogg Foundation
   c. Well organized state and local threshold and inservice training programs
   d. Programs of colleges and universities adequately staffed and equipped for sanitation training
2. Recognition of the place of technical specialists and trained sanitarians in administration and execution of sanitation programs by:
   a. Continuing the liaison between the Engineering Section and all related groups as started by the Policy Advisory Committee
   b. Continuation of the expansion of interests of the Section and Section programs to include all phases of environmental sanitation
3. Encouraging adoption of uniform codes and participation with industries in development of improved sanitary construction, operation and maintenance by:
   a. Standard ordinances proposed by the U. S. Public Health Service
   b. The program of the National Sanitation Foundation
4. Continued development and improvement of sound administrative programs and practices leading toward:
   a. Better means for determining and "selling" adequate numbers of sanitation personnel
   b. Coördination of programs with the health officers, the medical, nursing, and health education programs, and the state and other related official and nonofficial agencies
   c. Improved general administrative procedures.

Rural Sanitation*

Engineering Section

THE committee was first formed by action of the Engineering Section Council in February, 1947. The committee activities were expanded by the Section Council in October, 1948.

PURPOSE OF THE COMMITTEE

As amended in 1948, the objectives of the committee are now:

1. To gather factual information concerning rural water supply and rural sewage disposal practice in the United States.
2. To gather factual information concerning the status of progress on research in the design of rural water supply and sewage disposal systems.
3. To establish, if possible, standards of design acceptable to all federal, state, and local interests based on objective research and field information.
4. To coöperate in every way with federal, state, and local agencies charged with responsibilities for planning and approval of home water supply and sewage disposal systems.

NEW INFORMATION REPORTED IN 1948 ON HOME SEWAGE DISPOSAL

A. *U. S. Public Health Service Research*

The research project on sewage disposal sponsored by the National Housing Agency and the Public Health Service has developed considerable data in the last year. The work program was outlined in the 1947 report of this committee (see *Year Book 1947–1948*). The data had not been cleared by the sponsoring agencies in October, 1948, but should be released soon.

B. *Individual State F.H.A. Sewage Disposal Requirements*

The F.H.A. has added four to the list of states for which printed F.H.A. requirements are available. These are: Alabama, Georgia, New Hampshire, Wyoming. (See 1947 report for list of other states.)

C. *Engineering Section Committee on Rural Sanitation*

This committee has made a comparison of the recommendations for home sewage disposal in the several states and those of the Joint Committee. Information concerning the practice in 45 states is appended to this report.

The capacity for single tanks or the first compartment of double tanks varies from 300 gallons to 735 gallons. Thirty-two states recommended the same capacity as the Joint Committee recommends—500 gallons. Seven recommend less and 6 recommend more than that minimum.

The maximum number of persons allowed to use the minimum size tank ranges from 2 to 15. Only 1 state has a minimum below that of 4 persons recommended by the Joint Committee. Four states have the same recommendations and 29 are known to allow greater numbers to use their minimum size tank.

The tank dimensions mentioned by the Joint Committee are:

Length	72″
Width	36″
Water Depth	48″

Twenty-two states recommend the same length, 21 the same width, and 28 the same water depth.

The smallest minimum dimensions mentioned by the several reporting states are:

Length	54″
Width	24″
Water Depth	38″

* Progress Report.
COMMITTEE ON RURAL SANITATION.
Organized 1947. Published Report: *Year Book*, 1947–1948.

The corresponding higher minimum limits reported were:

Length	84"
Width	48"
Water Depth	60"

Four report less length, 4 less width, and 2 less water depth, while 1 reports more length, 2 more width, and 3 more water depth. Detailed length and width were not reported by 14 states and four establish the dimensions on the basis of each problem.

The Joint Committee suggests that either one or two compartments are allowable and 8 states agree. However, 23 recommend one compartment only and 5 recommend two compartments. Two have no specific recommendations and 7 did not report on this item.

There is a great variation in the minimum area of trench required for efficient disposal in sandy soil. The figures vary from 60 sq. ft. in 2 states to 666 sq. ft. in another state. Twelve follow that recommended by the Joint Committee—150 sq. ft.—but 11 report a lower minimum, and 10 report a higher minimum.

Minimum length of trench varies from 30′ to 525′ and minimum bottom widths vary from 12″ to 24″. The Joint Committee recommendation of 100′ length and 18″ bottom width is followed by 12 states for length and 15 states for bottom width. Eight states report less and 14 report more minimum length. Twelve states report less and 6 report more bottom width. Five states determine these dimensions and the total area on the base of percolation tests and have not specified a minimum length.

Cesspools as a means of disposal are not approved by either the Joint Committee or 24 states. Twelve approve cesspools for certain conditions, and 8 make specific recommendations on the basis of the problem.

Grease traps are not required in 20 states nor by the Joint Committee report. Four states do require them, and 6 states consider them optional. Thirteen states gave no information concerning this practice.

The several comparisons are detailed in Table 1.

It appears that several of the states may maintain dual standards; i.e., those recommended generally and those for use in connection with F.H.A. home loan approval. Further study is needed before a quantitative statement can be made.

It also appears that at least 14 of the states lack legal authority to enforce compliance with home sewage disposal standards.

D. *Definitions re Rural Sewage Disposal*

This committee for purposes of its work has adopted the following definitions. The committee will be glad to receive and consider any proposed modification of these definitions or a statement of definitions which the committee should seek to establish by clearance with all interested agencies.

1. Home sewage is the liquid waste from individual dwelling units.
2. A cesspool is an excavation which receives raw sewage from the home including kitchen and laundry waste.
3. A seepage pit is an excavation which receives effluent from a home sewage treatment process.
4. A dry well is a covered pit with open-jointed lining through which drainage from roofs, basement floors, or areaways may seep or leach into the surrounding porous soil.

E. *Research on Problems of Rural Sewage Disposal*

Information has been reviewed on the following research:

1. *University of Michigan, Ann Arbor—Prof. Earnest Boyce*

This study involves the operation under parallel conditions of a number of commercial septic tank systems as well as tanks designed and built in con-

vestigation of Small Septic Tanks." The university has entered into an agreement with a manufacturer of commercial tanks for the purpose of testing five tanks and determining which of three new designs is best. The work has been in progress for about one year.

4. *Purdue University, West Lafayette, Ind.—Prof. D. E. Bloodgood*

This involves a study of the development of a household incinerator for garbage and sewage.

5. *Conference of Municipal Public Health Engineers, Committee on Administrative Practice—W. H. Cary, Jr., Chairman*

This committee is studying the administrative procedures used in processing the construction and installation of new septic tanks. Reports have been received from ten local health departments in 1948. All replies lead to the tentative conclusion that public health engineering activities in local health departments should include some control of new septic tank installations. Further data are needed to confirm this conclusion.

INFORMATION ON RURAL WATER SUPPLY, 1948

A. *Joint Committee on Rural Sanitation*

The Joint Committee has published a companion to U.S.P.H.S. *Reprint 2461*, "Individual Sewage Disposal Systems." It is "Rural Water-Supply Sanitation," published as *Supplement 185* to the *Public Health Reports* of the U.S.P.H.S.

B. *Engineering Section Committee on Rural Sanitation*

This committee has begun a comparison of state standards for individual home water systems with the Joint Committee recommendations. Partial data have been compiled for 8 southeastern states. The committee will make the comparison available in its 1949 report.

C. *Research on Rural Water Supply Problems*

It does not appear that this field of research is receiving any marked attention at the present time.

The committee believes that research is needed on the following problems:

1. Requirements for protection of cistern water supplies
2. Treatment of home ground water supply containing excessive amounts of iron and manganese
3. Methods of continuous disinfection of home water supplies
4. Methods of disinfection of water lifted by hand pump

The committee would appreciate the receipt of information concerning research or standards now being developed by universities, official agencies, or individuals.

School Sanitation*

Engineering Section

DURING the first year of the committee's activity the objective was to develop a bibliography of material and standards covering the various subject matters in school sanitation. This bibliography was published with the report of last year and has been found useful to many sanitarians throughout public health.

A pattern was set at Ann Arbor last year in June for arriving at group judgment in the field of food control. It would seem that there is need for a clinic on school sanitation to iron out some of the variations in opinion in standards for school plant design.

Your chairman met with a committee of the National Council of Education on school house construction at which school administrators and architects met to consider the problem facing school administrators in the next ten years in the remodeling and revamping of present facilities and the construction of new facilities. It was conservatively estimated that $10 billion would be spent in this type of activity and that it would be highly desirable that some agreement be reached now as to details of building design from the various experts. Many of these problems do not involve public health, but all of them have to be considered by the architect before construction starts. Costly mistakes should be avoided. Old mistakes should not be perpetuated.

The report on the utilization of plumbing facilities which was made by the National Council of Education is still the best material available on that particular subject, which has pointed out the absurd variation in plumbing requirements of the various areas. The following of the standards suggested in their report will effect material savings.

The experimental work in lighting that has been carried out by the Illuminating Engineering Society Committee on Lighting is the best information available in that field. The experimental work conducted at Nela Park Experimental Station at Cleveland points the way to the latest thinking in light control and its application. Dr. Darell B. Harmon and others have been very successful in making field application of recommendations of the lighting engineers with the use of revamped window areas, more judicious use of color dynamics in painting the rooms, the selection of chalk boards that do not absorb light, and the use of shades to cover the chalk boards while not in use, all of which improve the quality as well as the intensity of light in existing structures without undue cost.

The work that has been carried out in sewage disposal by other committees is expected to point the way toward any improvement in septic tank installation that may be needed.

In connection with sewage disposal: Last winter in Michigan, during the extreme cold weather that existed during January, several school septic tanks and disposal fields froze. Six of these units were excavated while they were frozen and found to have ice on the tank

* Report of the Committee.
COMMITTEE ON SCHOOL SANITATION.
Organized 1947. Published Report: *Year Book* 1947–1948.

and in two cases ice in the tile field and in all cases the inlet pipe was frozen full. Several useful recommendations come from this experience. It was found, for instance, that by placing five pounds of salt daily in the toilet stool nearest to the frozen area that the ice plug would thaw out and several schools were able to put their system back into service by using this method.

The placing of sewer lines and septic tanks in schools where the eaves can drain onto the ground causing the soil to be saturated produced a condition that made it easy to freeze the lines. It was also found that paths worn by the children and the water from the eaves had eroded the ground in these areas so that the cover over the sewer line was packed tightly and was worn down several inches from the original grade. By placing additional fill and eave-troughs with down spouts in these areas it is thought that it would prevent a reoccurrence of these conditions.

The Study Group on Sanitation of the American Public Health Association, under the Subcommittee on State and Local Health Administration of the Committee on Administrative Practice, has suggested that grading systems be developed for all of these areas of environmental control, such as the grading system now used to grade a milk shed or a restaurant program. The Committee on School Sanitation this year has collected several grading procedures to determine if any of the systems that are now being used are suitable to rate the status of school sanitation in an area. All of the systems that have been reviewed to date involve a numerical percentage point assigning a weight to each item scored which totals 100 per cent for all the items. It is obvious that there are certain key items that are important enough so that a substandard condition should be assigned enough points to degrade the school in a poor class. A good example of this would be water supply or sewage disposal. In other words, if the water supply was found to be unsafe or the sewage disposal insanitary, it is a condition which should receive high enough penalty points to score the school substandard and potentially dangerous.

The Michigan Department of Health has used a system of colors, which gets around the numerical rating, and if any key item is found to be substandard the color arrangement is developed in such a way that the entire school would be scored a poor color. While this works very well on an individual school, it is not practical on an area basis.

The Committee on the Hygiene of Housing has developed a system of penalty points which is the reverse of the system used in rating a milk shed or the ones that are now used in school sanitation. This system assigns penalty points to items that are in non-compliance, and if every item were satisfactory the score for the school would be zero. In this way it is possible to exceed 100 penalty points to any extent necessary. This system has worked very successfully with housing and certain items are scored as basic deficiencies, which are considered the important items. Such a scoring system might well be developed for rating schools.

There is not a uniform group of items used by sanitarians for grading schools. The committee has developed a list of broad topics that are thought to be important in inspecting schools (see Table 1).

There are standards now available that are uniform for most of these items. The items of safety, hall widths, stairway construction, exits, and fireproofing are available through the recommendations of the National Board of Fire Underwriters, New York City. The utilization of sanitary facilities which suggests the number of toilets, drinking fountains, and lavatories is available through the American Council of Education,

TABLE 1

Group I	*Group II*	*Group III*
Site	Water supply	Sewage disposal
Structure	Drinking fountains	Refuse disposal
Rooms	Food Equipment	Source of food
Seating	Showers and Locker Rooms	Handling procedure of hot lunch program
Heating and ventilating	Swimming pool	
Lighting	Handwashing facilities	Housekeeping
Safety	Toilet facilities	

Washington, D. C. An abundance of material and suggested standards of lighting, painting, and color choices is available through most paint manufacturers and power companies.

The arrangement of school furniture and the most desirable types of seating is fairly well agreed upon by the educators. The seating should be moveable and adjustable.

Answers are still needed in some items, such as:

1. Is open window ventilation satisfactory?
2. Where mechanical ventilation is used, how many cubic feet of air per child is required?
3. How much, and under what circumstances, can air be recirculated safely?
4. What are the optimum temperatures and humidity conditions for health and learning?
5. Is air conditioning feasible and economical under typical school conditions?
6. How much water is consumed per pupil?
7. How much septic tank capacity should be provided per pupil?
8. How much floor space should be provided per pupil?
9. What are satisfactory methods of dishwashing and food handling in rural schools?
10. How should the floor be treated and what are suitable coverings for the floor?

The American Council on Education is making an effort to find financial assistance to hire a staff to investigate these problems and to set up a clearinghouse for information and useful ideas. The Committee on Educational Plant and Equipment recommended a research project which would extend for three years at a cost of $50,000 per year to work on problems of school plants and equipment. Such a project is needed to find the best answers to these problems and could save many dollars in future construction.

The problems in school sanitation divide themselves into four classifications:

1. The one or two room rural school, which produces its own water supply and provides its own sewage disposal facilities on the school site and is constructed with or without a basement.
2. The consolidated school, located in a rural area, which has its own water supply and sewage disposal facilities.
3. The graded school or high school unit found in the average urban community.
4. The large urban school or college which has groups of buildings and grounds.

The problems in each of these schools are materially different and need special study and application. To date, the committee has been concerned primarily with the first three classifications with the bulk of the emphasis on the first classification.

Water Supply*

Engineering Section

RECENT reports of this committee have discussed important trends which pertain directly or indirectly to the quality of public water supplies. This policy has been continued this year.

The high cost of material and labor and the unsettled economic conditions have led to the postponement of many improvements to water supply systems and to an increase of as much as 250 per cent in the cost of construction work as compared with pre-war conditions. This unfortunate situation is resulting in still further prolonging the delayed maintenance characteristic of the depression period and the subsequent war period. As a result, many water supply systems are overloaded and are in urgent need of repair and expansion. A survey of water supply needs by the U. S. Public Health Service discloses estimated construction costs as of 1947 to be $2,269,000,000, of which 17 per cent was for projects ready for construction, 27 per cent for those being planned, and 56 per cent for those considered to be future projects.

The estimated population of 2,360,000, residing in small communities not served by public water supply systems, is of public health significance, because many private wells in such communities have been found to be subject to pollution because they must of necessity be located close to potential sources of pollution. Public water supply systems needed to supersede these private wells are considered to be practicable for communities as small as 200 population. Health officials should support this essential construction program.

More attention is being given to water resources and to long-range planning as to the appropriate use of such resources. A Water Resources Division of the American Water Works Association was organized this year. There is growing interest in the development of standards of well construction. State organizations of well drillers are becoming active. It is very evident, therefore, that public health engineers should consider the role of health departments in the licensing of well drillers, the enactment of official well codes, etc. There are so many aspects to this subject that great care must be exercised in the development of state programs so as to avoid inconsistencies and thus retard developments on a nation-wide level.

WATER-BORNE DISEASES

The stream pollution abatement programs under way in a number of states, supplemented and coördinated by federal government under provisions of recent legislation, have led to considerable popular literature on the subject which focuses attention upon water-borne diseases as justifying stream pollution abatement. Unfortunately, much of this literature is so misleading as to give the impression to the layman that most public water supplies are secured from sewage polluted streams, and conversely that the mere installation of sewage treatment plants will lead to safe water supplies.

A reëxamination of the statistics of

* COMMITTEE ON WATER SUPPLY.
Organized 1922. Published Reports: *A.J.P.H.*, Sept., 1924, Apr., 1925, Feb., 1926, July, 1927, Apr., 1928, Feb., 1929, May, 1930, *Year Books* 1930–1931, 1931–1932, 1932–1933, 1934–1935, 1937–1938, 1939–1940, 1940–1941, 1941–1942, *A.J.P H.*, July 1945, May, 1947, Feb., 1948.

water-borne diseases was made recently by Eliassen and Cummings[1] so as to focus attention upon the generally satisfactory character of public water supplies, but at the same time to indicate improvements in technique and control which are needed to reduce further the incidence of water-borne diseases, especially among those served by private and semi-public supplies of institutions and summer resorts in rural areas. In other words, sanitation including water supply supervision must be brought to the rural population which often lives under conditions of exposure characterized by urban communities in pre-sanitation days.

Gastroenteritis continues to present a baffling technical problem. It would seem that much gastroenteritis is spread by contaminated food or by direct contact under insanitary conditions. Water-borne gastroenteritis also is associated with insanitary conditions. Frequently such outbreaks are found to be mild bacillary dysentery. The continued prevalence of obscure outbreaks, where no known pathogens have been isolated from stool specimens, led to a research program by the New York State Department of Health.[2] Preliminary results indicate that at least one type of virus has been isolated. Volunteers have been infected by the oral route under laboratory conditions. It has not been demonstrated as yet, however, whether this virus actually is transmitted by polluted water supplies nor is there any information as to the susceptibility of the virus to the action of chlorine. It may be that the virus is spread primarily by contaminated food or by direct contact under insanitary conditions. These studies are being continued.

Previous reports of this committee have discussed the lack of epidemiological evidence that poliomyelitis is spread by water supplies. Nevertheless the virus has been isolated from sewage and thus the committee has felt justified in drawing attention previously to the disclosure that the virus is susceptible to the action of conventional concentrations of free residual chlorine. Unpublished results of the continued studies by the Michigan Department of Health have indicated that this effectiveness is restricted to the range of lower pH values, but that lime-soda softened waters should be prechlorinated before the alkali is added to insure satisfactory destruction of the virus. We understand that at least one city in Michigan is planning a prechlorinating contact chamber for this purpose.

TOXIC ALGAE

Domestic animals have been reported as dying following the consumption of surface waters containing prolific growths of blue-green algae. The conclusion has been reached that this may be due to the cyanide content of such aquatic vegetation. As far as the committee could learn through a nation-wide questionnaire answered by the public health engineers of 39 states and 2 territories, there is no known instance where such toxic effects have been noted among human beings. The inference is that potable waters containing such prolific growths of algae would not be consumed. This subject is being studied at the University of Minnesota.

TRACE ELEMENTS IN POTABLE WATERS

The physiological benefits of small concentrations of iodine, fluorine, copper, etc., in potable waters, and conversely the toxic characteristics of somewhat higher concentrations of these and other elements, coupled with the recent disclosure that nitrates in excess of 10–20 p.p.m. may lead to cyanosis among infants, or that high concentrations of sodium may aggravate certain cardiovascular disorders, has focused attention upon trace elements in potable waters. The subject is being investigated at Johns Hopkins University and

elsewhere. It is very evident that more specific information is needed to forestall the popular misconception as to possible harmfulness of small concentrations of constituents in potable waters which heretofore have been ignored. In this connection it is pertinent to refer to an article by Levitt[3] which would be misleading to the layman in that the alleged harmful influence of small concentration of chlorine, fluorine, and bromine appears to be based upon definite data resulting from scientific research and extensive review of technical literature. Actually, the paper is very unsound technically—for instance, where residual chlorine which may remain temporarily in treated potable water is stated categorically to be responsible for degenerative processes, but where, for instance, the supporting argument gives no recognition to the fact that free chlorine very quickly is converted to the chloride ion and thereafter is identical to the ions of common salt present in much higher concentrations in food. While this article should not be taken too seriously it is being cited as a concrete example of confusion which prevails as to the physiological significance of trace elements in potable waters. Such confusion may well retard the progress of sanitation.

CYANOSIS DUE TO NITRATES IN POTABLE WATER

The significance of nitrates in potable water used in the preparation of formulae for infant feeding is being discussed at this session. It is pertinent at this time, however, to summarize the results of the nation-wide questionnaire of the committee which discloses the following situation:

Surveys have been reported in 13 of 39 states and 2 territories furnishing data. Concentrations of nitrates exceeding 20 p.p.m. in shallow, rural well waters have been noted in areas of 10 states. For instance, about 50 per cent of private wells in North Dakota so far examined yield water containing more than 20 p.p.m. nitrates. Concentrations of nitrates as high as 500 p.p.m. have been reported in 12 states and in Alaska. Actual cases of cyanosis, however, have been reported in only a few states, including North Dakota, where only 10 cases are known to have occurred in spite of the large number of rural wells containing over 20 p.p.m. nitrates.

Cornblath and Hartmann[4] recently concluded that only infants are involved because the pH of 4.0 or higher of their gastric juice enables nitrate reducing bacteria to function and form nitrites in the upper intestines, whereas the more acid gastric juice of older children and adults insures the assimilation of the nitrates before they are subject to this reducing action.

The surveys now in progress in a number of states, therefore, are needed to clarify this situation.

TOXIC METALS

The Drinking Water Standards of the U. S. Public Health Service now list the following metals as being toxic above the concentrations noted:

Lead, 0.10 p.p.m.; fluorine, 1.5 p.p.m.; selenium, 0.05 p.p.m.; and hexavalent chromium, 0.05 p.p.m.

Suggested upper limits are given for the following metals:

Copper, 3.00 p.p.m.; and zinc, 15.0 p.p.m.

The situation regarding the toxicity of chromium is somewhat indefinite because the toxic concentration noted above has been reported as being based upon transposition of values secured in the study of the toxicity of chromium dusts in industry. This uncertainty is under investigation. The nation-wide questionnaire circulated by this committee discloses that chromium wastes have been a problem in only 7 states and only then to a limited extent. Chromium is not an ingredient in natural waters but is incidental to the discharge of industrial wastes from aluminum anodyzing plants of the airplane industry.

The discharge of such wastes through percolation beds on Long Island in the absence of surface streams, has led to the pollution of ground waters, so that

concentrations of hexavalent chromium as high as 1.5 p.p.m. have been encountered in nearby well supplies. Because of this situation treatment facilities are under construction at 1 plant and are under design at 3 other plants, based upon established treatment procedure where the hexavalent chromium is reduced to the trivalent form, following which lime is added to form insoluble chromium hydroxide, which precipitates as a sludge. Similar plants have been installed in several other states.

Cadmium also is receiving attention as a toxic metal. Cadmium plating of plumbing fixtures has been reported but there is very limited information as to the possible future signifiance of this practice. Incomplete evidence seems to indicate that cadmium may be toxic when present in concentrations exceeding 0.5 p.p.m.

It is anticipated, therefore, that these problems will receive much greater attention now that extensive airplane construction is being resumed, and where new materials and industrial processes are being utilized.

CHLORINE DIOXIDE TREATMENT

The use of chlorine dioxide to destroy taste and odor producing compounds has received wide publicity. It is significant at this point to draw attention to research as to the disinfection characteristics of chlorine dioxide by the Massachusetts Department of Health and at the University of Michigan.[5] Tentative conclusions have been reached that chlorine dioxide appears to have disinfecting properties which are less affected by high pH values than equivalent concentrations of free residual chlorine. If these results are substantiated by studies with water of varying characteristics, it would seem that progress has been made in the disinfection of water having a high pH value incidental to corrosion prevention or lime-soda softening treatment.

CHLORINE RESIDUAL RECORDER

Ordinarily this committee would not refer to a single example of commercial water purification equipment, but the recent development of the chlorine residual recorder appears to represent an important stage in water chlorination practice. Experience at 14 installations has shown that the chlorine demand of water supplies fluctuates to a more marked degree than usually realized. In fact, these fluctuations have been correlated at some plants with details of operating control not usually associated with chlorination. Obviously the recorder permits closer control of chlorination within limits producing best results for a given water. The next logical development is the use of this equipment to control the dose of chlorine so as to maintain automatically a uniform concentration of residual chlorine in the treated water. Inasmuch as faulty operation of water purification plants has been found to be the cause of a number of outbreaks of water-borne disease, this development is of distinct public health importance.

BROMINE AS A DISINFECTANT

The nation-wide questionnaire distributed by the committee has indicated that bromine has been experimented with in several states but that it was used for a few years in the treatment of only a few public water supplies in one western state. Practical experience, therefore, is restricted to Illinois[6] where the water in 45 swimming pools has been disinfected for from 1 to 8 years. Bromine appears to be about as effective as chlorine as a disinfectant when present in equivalent concentrations. Its use in swimming pools is reported to produce less irritation of the eyes and throat and less taste and odor than comparable concentrations of chlorine. The bromine demand of water of high organic content, however, exceeds the comparable chlorine demand and resid-

ual bromine is less stable than residual chlorine. Bromine is reported as costing from 4 to 7 times as much as liquid chlorine.

Equipment for the application of bromine to water has not as yet been developed comparable to well established chlorinators. This disinfectant, however, warrants further study.

CIVILIAN DEFENSE

There has been considerable concern on the part of public health officials regarding potential hazards involved in the production and distribution of radioactive materials and particularly in the disposal of wastes resulting from their production and use. Much of this concern undoubtedly has risen from lack of available information with respect to the character of these wastes and adequacy of present methods of removing them from waters which have been contaminated.

The Armed Forces and the Atomic Energy Commission have recognized this problem and conducted courses of study for selected personnel who, in the event of disaster, could act in an advisory capacity to direct control measures.

The Atomic Energy Commission is receiving coöperation from the U. S. Geological Survey, the U. S. Public Health Service, and the U. S. Weather Bureau in considering disposal of liquid and gaseous waste at its various operating areas. In addition, a research program has been organized to study the effect of radioactivity on the more common biological processes used in sewage treatment.

During the past 2 years there has been a marked increase in the number of shipments of radioisotopes for use in medical and other research institutions. There has been concern on the part of public officials regarding unregulated discharge of wastes resulting from the use of these materials into public sewer systems. This problem is also under investigation by the Atomic Energy Commission.

The Office of Civilian Defense Planning has prepared a report covering all phases of national defense which includes a special section on public health activities. This document, which is unrestricted, is scheduled for early publication and distribution.

CONCLUSION

It is evident, therefore, that the supervision of public water supplies by health officials still presents many problems and opportunities and that the public health importance of this activity is not disclosed by typhoid fever statistics, nor can it be overlooked while exploiting novel or new aspects in the control of the environment. The financing of improved and expanded water supply systems and technical problems requiring basic research represent the outstanding challenges.

Food and Nutrition*

THE Food and Nutrition Section held two independent and five joint sessions in connection with the 76th Annual Meeting of the Association in Boston, Mass., November 8–12, 1948.

The program and attendance follow:

Independent Session "Food Production and Processing in Relation to Conservation of Nutrients"	200
Joint Session with Laboratory "Milk"	165
Independent Session (held concurrently with joint session on "Milk") "Nutrition in Public Health"	175
Joint Session with American School Health Association "Child Nutrition"	220
Joint Session with Laboratory "Nutrition in Infection"	300
Joint Session with Health Officers, Laboratory, and Engineering "Sanitary Practices in the Food Industry"	216
Joint Session with Maternal and Child Health and Public Health Nursing "Content of Maternal and Neonatal Health Services"	400

MINUTES OF THE ANNUAL BUSINESS MEETING

The membership of the Nominating Committee was read by the Secretary at the opening of the first session at 9:30 a.m. Tuesday, November 9.

The business meeting was called to order at 11:30 a.m. Tuesday, November 12, by Marjorie M. Heseltine, Section Chairman.

The following committee reports were accepted:

Sanitary Practices in the Food Industry, Harry Goresline, *Chairman*

Committee on Standard Methods for Microbiological Examination of Foods, Harry Goresline, *Chairman*

Nominating Committee—Chairman presented the following slate:

Chairman—Harry Gorseline
Vice-Chairman—Paul Prickett
Secretary—Alice Smith
Councilor—(for the term ending 1953) Frances McKinnon
Representative on A.P.H.A. Committee on *Eligibility* *—Marjorie M. Heseltine
Representative on A.P.H.A. Governing Council, Nominating Committee—Ethel A. Martin

There were no nominations from the floor and the Secretary was instructed to cast a unanimous ballot for the slate presented by the Nominating Committee. (See changes listed under "Officers and Council Members" in report of Section Council Meetings.)

Marietta Eichelberger, *Chairman*, Nominating Committee
Fred Tanner
Henry T. Scott
Rachel Reed

Membership and Fellowship

The Chairman was inactive during the year and absent from the business meeting. The Secretary submitted the following report:

	9-1-1947	*9-1-1948*	*11-1-1948*
Members	439	452	452
Fellows	106	104	111
Total	545	556	563

The membership is evenly divided between those in the field of Food and those in Nutrition.

Thirty-nine applied for Fellowship and 38 were approved by the Section Council and submitted to the Association's Committee on Eligibility.

Dr. Kimball, Chairman of the Goiter Committee of the American Public Health Association, American Medical Association, U. S. Public Health Service and the State and Territorial Health Officers Association, gave a progress report of that committee and included a comment on proposed legislation for 1949.

Resolutions

Dr. Glen Slocum, Chairman of Resolutions Committee, read the following Resolutions:

School Lunch Program

WHEREAS, the service of nourishing noon meals at school is an important part of a program of health services and health education for children of school age; and

WHEREAS, the benefits of school lunches are freely available to all children only where public funds defray a substantial part of the cost of food, service, and administration; and

* Report of the Food and Nutrition Section Secretary.

* 2 year appointment

WHEREAS, federal, state, and local appropriations during recent years have not increased sufficiently to keep pace with rising costs of food and labor for preparing lunches, therefore be it

RESOLVED, that the American Public Health Association hereby endorses continued federal support under the National School Lunch Act and adequate state appropriations for matching federal funds and for the efficient operation of the program.

Red Cross Nutrition Service

WHEREAS, the current high costs of living in general and of high food costs in particular threaten the adequacy of family diets, and

WHEREAS, studies have shown that effective community education programs enable homemakers to obtain the maximum return in money expended for food, and

WHEREAS, local chapters of the American Red Cross are uniquely equipped to offer such an educational program, especially in urban areas, therefore, be it

RESOLVED that the American Public Health Association convey to the appropriate individuals its hope that this community nutrition service be continued and that chapters can continue to count on adequate consultation and other assistance from national and area offices.

It was moved and seconded that both resolutions be submitted to the Association's Committee on Resolutions for consideration by the Governing Council. The first resolution was adopted. The second was reported received.

Meeting adjourned—12:15 p.m.

MINUTES OF THE MEETINGS OF THE SECTION COUNCIL

Two meetings were held. The *first* meeting was called to order on Monday, November 8, at 4:00 p.m.—adjourned at midnight.

Officers and councilors present were:
Marietta Eichelberger
Harry Goresline
Marjorie M. Heseltine, *Chairman*
Margaret C. Moore
Alice Smith, *Secretary*

The *second* meeting was called to order on Thursday, November 11, at 12:15 p.m.—adjourned at 2:15 p.m.

Those present were:
Marietta Eichelberger
Harry Goresline
Marjorie M. Heseltine, *Chairman*
Frances McKinnon
Margaret Moore
Alice Smith, *Secretary*

Order of Business:

I. *Fellowship and Membership*

In the absence of the Section's representative on the Association's Committee on Eligibility (Mr. Ole Salthe), Miss Marjorie M. Heseltine again represented the Section. Thirty-nine applications for Fellowship were reviewed by the Section Council. Thirty-eight of them were submitted to and approved by the Committee on Eligibility. All membership applications published in the *Journal* and not approved by the Section Council were approved at this time.

II. *Progress Reports*

A. Merit System—In May, Miss Catherine Leamy assumed responsibilities of nutrition consultant to the Merit System Unit of the American Public Health Association. Miss Leamy has been reviewing and writing questions. Twelve public health nutritionists throughout the country are assisting with the preparation of questions.

B. Food and Nutrition Board—The secretary was instructed to relay to Dr. Atwater a memorandum recommending that the Association Executive Board submit to the National Research Council a request for the appointment of a liaison member from the American Public Health Association to the Food and Nutrition Board of the National Research Council.

In the event that such an invitation is extended to the Association, it would seem appropriate that an officer or a member of the Council of the Food and Nutrition Section serve as liaison member. The Section Council would like the opportunity to name the Association representative.

C. Program—The Secretary reported that the technique of canvassing Section members for program suggestions was a successful one and is worthy of repetition.

III. *Committee Reports*

A. Committee on Sanitary Practices in the Food Industry—Harry Goresline, *Chairman.* This committee was formed after the 1947 Annual Meeting, and plans to "bring together the available information in the field of sanitation, as it applies to the handling, processing, storing, transporting, and serving of food products, and from that information prepare a manual of effective, reasonable, and workable sanitary practices for the guidance of those engaged in, or dealing with the food industry." A preliminary outline of subjects to be covered in the proposed manual has been circulated to committee members and subject matter has been assigned to some members. The committee of fourteen has representation

from the Health Officers, Laboratory, Engineering, and Food and Nutrition Sections.

B. Committee on Standard Methods for the Microbiological Examination of Foods—Harry Goresline, *Chairman*. Dr. Goresline's report was on "Tentative Methods for the Microbiological Examination of Dehydrated Fruits and Vegetables." Dr. Goresline reported that work needs to be included on Precooked Frozen Foods and on Mayonnaise and Salad Dressing. The complete report has been submitted to the Association's Coördinating Committee on Research and Standards. The Committee on Microbiological Examination of Foods will no longer function as a section committee, but rather as a subcommittee of the Coördinating Committee on Research and Standards. Dr. Goresline has accepted the invitation to serve as chairman this year.

C. Committee on Research and Standards—Lloyd Jensen was appointed as the Section's representative. Dr. Jensen was not present and no report was submitted. The minutes of this committee's meeting were circulated to Section Council members at an earlier date.

IV. *New Committee*

Several members of the Section requested a committee be appointed to consider the implications for health and nutrition of some of the newer Practices in Food Production and Processing—this is to include insecticides, spray residues, food adjuncts, mold inhibitors, etc. Suggestions for committee membership are being sent to the chairman for consideration.

V. *Officers and Council Members*

Dr. Goresline submitted his resignation as Section Chairman. This action was prompted by his interest in and acceptance of the chairmanship of two committees. The chairman of the Nominating Committee was asked to review the deliberations and considerations of the committee, and present nominations to the Council. The Council elected Paul Prickett as *Chairman*. Since Dr. Prickett had been elected vice-chairman, he was contacted, resigned as vice-chairman, and accepted the chairmanship. This left a vacancy in the office of vice-chairman — Margaret Moore was elected. Miss Moore's unexpired term of Councilor was then filled by William H. Sebrell, Jr., M.D.

VI. *Rapporteur for Annual Meeting*

Fredrick Stare was appointed the Food and Nutrition Section's representative for reporting the highlights of the sessions at the summarizing general session. Dr. Stare chose to comment on only one paper.

VII. The Secretary submitted names of several members to Dr. Atwater to be invited to study and evaluate exhibits along with representatives of all other Sections.

VIII. *Editorial Board Luncheon Meeting*

Friday noon, November 12, the officers and councilors were the guests of the Editorial Board at a luncheon—the fee for which was "the grading of the papers presented at the annual meetings." This meeting was attended by the same persons who attended the Section's second Council meeting.

The Section officers and councilors, and especially the Secretary, wish to take this opportunity to thank all the members for their coöperation throughout the year.

We wish particularly to thank Dr. Atwater, Mrs. Walsh, and Miss Siemer for their many suggestions and the work they performed for the members.

ALICE H. SMITH, *Secretary*

Sanitary Practices in the Food Industry*

Food and Nutrition Section

THE Committee on Sanitary Practices in the Food Industry was formed after the 1947 meeting of the Association and has spent the year in organizing, clarifying the field of activity, and in laying out the work to be done. The committee was formed to bring together the available information in the field of sanitation, as it applies to handling, processing, storing, transporting, and serving food products, and from that information to prepare a manual of effective, reasonable, and workable sanitary practices for the guidance of those engaged in, or dealing with the food industry. Realizing that the field was broad and that the interest of various groups was involved, the committee was made up of representatives of the Engineering, Health Officers, Laboratory, and Food and Nutrition Sections of the Association. Each Section was asked to suggest those members having a definite interest in this type of work and who could prepare authoritative material. A representative committee of 14 members was made up from this list.

In keeping with the above objectives, the four Sections agreed to hold a joint session during the 1948 annual meeting, the program to deal with sanitary practices in the food industry. A program of 6 papers dealing with different phases of the subject was organized during the year for this joint session.

A preliminary outline of the subjects to be covered in the proposed manual was circulated to the committee membership and some agreement reached as to the manner in which the manual should be prepared. It has been tentatively agreed that the manual shall take the form of a series of discussions covering the principles and practices of sanitation as background material, followed by discussions on specific problems of individual food industries.

Members of the committee were asked to assume responsibility for certain sections of the manual and at the present writing about one-half of the general subject matter has been tentatively assigned. It will be necessary to go outside the committee for assistance in preparing certain sections, particularly those dealing with specific food industries.

In order to bring about a better understanding between committee members regarding the work to be covered and the manner in which the material is to be presented, a conference of 8 members of the committee has been arranged during the annual meeting. It is believed that during the conference plans can be completed for the work of the committee and the scope of the work outlined more clearly.

Report of the Archivist, 1948

Laboratory Section

THE Section is indebted to Dr. Edmund K. Kline and, more recently, to Dr. Geoffrey Edsall, as *Secretary*, for maintaining the regular deposit in the archives of the minutes of the Section Council and of reports on Section Meetings. Dr. Friend Lee Mickle deposited copy of the minutes of the final meeting of the Section Coördinating Committee on Standard Methods, held October 8, 1947; and also copy of Dr. Robert S. Breed's resignation dated October 1, 1947, as *Chairman* of the Editorial Committee of the Standard Methods for the Examination of Dairy Products, the ninth edition of which has now been published. Dr. Breed's review in this letter of his connection with the work from 1909 is a pertinent archival note. A further deposit from Dr. Kline during the year is a letter from Dr. Mazÿck P. Ravenel, written September 23, 1941, with recollections of various notable figures in the field of bacteriology during the past fifty years.

Other members of the Section have also remembered the archives. Throughout the year scattered replies were received to the 1947 canvass of activities related to World War II. Photographs were given by Dr. Thomas A. Hart, Roosevelt College, Chicago, and Dr. Gustave J. Dammin, Washington University School of Medicine, St. Louis, and Director of Laboratories, Barnes Hospital. Dr. Dammin called special attention to the U. S. Army film, "Army Medical Laboratories." He was technical adviser for the film and asked that arrangements be made for its presentation in the film displays sponsored by the Association at the Boston meeting. It shows many excellent scenes of Army laboratories, and Dr. Dammin believes it contains material of value in relation to the archives of the Section. One of Dr. Dammin's interesting photographs, taken in 1944, is of the laboratory of Dr. Seagrave's hospital in Burma serving Chinese troops.

A valuable unit of the archives is the collection of photographs and biographical records of the officers of the Section. I thought it might interest you to see how this collection is maintained, so a simple exhibit has been made of the photographs of the officers at the time of the previous meetings of the Association in Boston in 1905 and 1922: In 1905, Dr. William H. Park, New York, Chairman; Dr. Harry W. Clark, Boston, Vice Chairman; Dr. John J. Fulton, Baltimore, Secretary; Dr. H. D. Pease, Recorder: in 1922, Dr. Frederick F. Russell, Chairman; Dr. A. Parker Hitchens, Vice Chairman; Dr. John F. Norton, Secretary.

Also shown in the exhibit is a program of the 33rd Annual Meeting, September 25–29, 1905, in Boston. Dr. Theobald Smith was the first Chairman of the Laboratory Section after its formal organization in 1900 and in the program of 1905 is found one of his now historic contributions, "The Fermentation Tube in the Study of Anaerobic Bacteria with Special Reference to Gas Production and the Use of Milk as a Culture Medium."[1] His paper was followed by one by Dr. Oskar Klotz, Montreal, on "Temporary alteration of character in an organism belonging to the colon group,"[2] which Dr. Smith discussed. Among the collection of papers received from Dr. Pease, Re-

corder, and which are the body of early archival material available, it was interesting to recognize Dr. Smith's original pencil note of this brief discussion [2a]:

"Dr. Klotz's paper is very interesting and suggestive. Much is still to be done to determine how much bacteria may vary under changing conditions. My own observations of a large number of cultures of *B. coli* and its variants lead me to regard the gas production and gas formula as a very stable function. I have never seen any change in cultures in my hands, although I have kept them for years. It seems, however, as brought out by Dr. Klotz and in an earlier paper by Mr. Fuller, that the gas production of the colon bacillus may be temporarily aberrant when the organisms have been in an untoward environment. Whether the character can be wholly altered by a persistence of such environment is a question of very great importance."

The deaths of the following members of the Section are recorded with regret:

Karl R. Bailey, M.D., Boston, Mass.
Elected member 1946

Fred Boerner, M.D., Philadelphia, Pa.
Elected member (1943)

Elizabeth C. Brown, Columbia, Mo.
Elected member 1938; Fellow 1942

Harly A. Bunner, Atlanta, Ga.
Elected member 1946

Hyman M. Charm, Sc.D., Bronx, New York, N. Y.
Elected member 1937

Joe Davis, Seattle, Wash.
Elected member 1943

Conrad Kinyoun, Savannah, Ga.
Elected member 1926, Fellow 1933

Leslie A. Sandholzer, Ph.D., College Park, Md.
Elected Member 1940, Fellow 1944

Commission for the Study of Biological Stains*

Laboratory Section

DURING the past year the Stain Commission has completed the removal of its activities from the New York State Agricultural Experiment Station in Geneva. Laboratory activities, both chemical and biological, are now carried on in the University of Rochester, and business and editorial offices are located in a business office in Geneva.

Dr. H. J. Conn, the President of the Commission, who has served so faithfully since its inception retired from the Staff of the Agricultural Experiment Station, May 1, 1948, and is devoting his full time to Stain Commission activities. During the coming winter Dr. Conn plans to spend several weeks on a trip to the West Coast to promote the activities of the Commission.

Routine examination and certification of new lots of stains before they are placed on the market has been continued as heretofore, approximately 65 lots of dyes being completely tested both chemically and biologically prior to certification in the past year.

It has been possible to obtain a number of German made stains subsequent to the war and many of these have been tested in the laboratories of the Commission in comparison with present-day dyes of American manufacture, with the American stains showing a general superiority. This work will be continued and reported in more detail at a later date.

Publication activities have also been continued along the lines followed in past years. *Stain Technology*, the quarterly journal, has become a problem because of the large amount of excellent material that is presented for publication. Until the present time about 150–160 pages were published annually. This year's volume will amount to about 232 pages, an increase of some 44 per cent. It has been decided to increase the size though this will make it necessary to raise the subscription price by $1.00 per annum.

A new Second Edition of the book *History of Staining*, by Dr. Conn and collaborators was published early in the fall of 1948 after the text had been out of print for over a year. An index of all material contained in the various leaflets on Staining Procedures was prepared and published, in March, 1948. One leaflet has been revised and reissued this year (*Animal Histology; Miscellaneous Methods*).

Research grants have been continued and at present are being given to three universities: Rochester, Northwestern, and McGill. Additional grants for research are possible.

Income from the various projects of the Commission exceeded operating expenses by a comfortable margin as in several immediate past years. However, research grants are not considered as a part of operating expenses and have in part been paid out of capital funds of the Commission, reducing these funds by about 2 per cent.

Once more members of the American

* Report of the Association Representative. Published Report, *Year Book* 1947–1948.

Public Health Association who are interested in problems dealing with stains as related to bacteriology are invited to seek the coöperation of the Stain Commission. Perhaps we can jointly work out a program for further investigations of your problems.

EDMUND K. KLINE, DR.P.H.,
Association Representative on the Biological Stain Commission

Camps and Camping*

Maternal and Child Health Section

I. WHAT CONSTITUTES RECREATION CAMPS

THE following shall be regarded as constituting recreational camps.

All places of camping character, as the term is commonly understood, which are utilized wholly or in part for recreational purposes and operated for a period of 30 days or more during one or more seasons of the year, whether continuously or otherwise, and which receive the patronage, whether paid or not, of five or more children who are not bona fide personal guests in the home of an individual, and any of which children, not accompanied by parent or guardian, is under 18 years of age.† Such patronage may be for recreational purposes solely or for a combination of recreation, health, and instruction, and may be for profit or under philanthropic or charitable auspices.

II. CAMP SITES

A. *Camp Location and Upkeep*

1. Camps should be located on suitable and well drained grounds of sufficient area adequately to meet needs, free from natural hazards such as mosquitoes, ticks, poisonous snakes, etc., that may be prevalent in the area. The soil should be suitable for the disposal of wastes by the method contemplated.

Roads, trails, and walks for the use of the camper and public, in connection with the camp, should be so guarded or posted as to insure safety.

The premises and equipment should at all times be kept in a clean and safe condition and free from vermin.

Areas immediately adjacent to buildings, council rings, paths, etc., should be freed of poison ivy, poison oak, etc. Some new chemicals such as ammate or 2,4-D are highly efficient for this purpose.

III. BUILDINGS, SLEEPING QUARTERS AND EQUIPMENT

1. All buildings, tents, vehicles, and grounds should be maintained in a clean, sanitary condition at all times.

2. Adequate sleeping place should be provided for each person. No room used for sleeping purposes should have less than 600 cu. ft. of air space for each occupant.

3. Ventilation in sleeping quarters, kitchens, dining rooms and mess halls should provide a reasonable movement of air at all times and assure the comfort and protection of the occupants.

4. The doors, windows and other outer openings of kitchens, dining halls, and sleeping quarters should be adequately screened, where health or comfort of the campers warrants it.

5. All floors should be sufficiently raised above the ground so that they will remain dry.

6. The area of window space in each sleeping room should be equal to at least one-eighth of the floor area of the room.

7. Windows of sleeping rooms should be so constructed that at least half of each window can be opened.

8. Any permanent buildings in which persons are housed should provide ready exit in case of fire. Fire extinguishers or other fire fighting apparatus must be

---

* Report of the Committee.
COMMITTEE ON CAMPS AND CAMPING.
Organized 1942.

† This refers to the organized type of camp with permanent or semipermanent facilities.

adequate and should be placed where easily accessible. When chemical extinguishers are used, they should be inspected and tested immediately before the opening of camp and at least every 2 months during the camping season. Where water buckets or pails of sand are provided, they should be checked weekly. Water buckets should be protected to prevent mosquito or other insect breeding. Two suitable exits should be available for each semi-permanent or permanent structure.

IV. ADMINISTRATIVE PERSONNEL

1. There should be a responsible person in charge of the camp, present in the camp at all times so long as campers are present.

2. Some member of the camp staff should be charged specifically with the responsibility for the sanitation of the camp.

3. In general, the camp nurse or physician is too busy to carry on the additional work involved in health education. This is best done by group leaders or counselors. Special training may be necessary for these leaders. Likewise, the routine cursory daily check for obvious symptoms of illness can best be given by the group leaders or counselors, provided they have had some instruction from the camp physician.

V. CAMP WATER SUPPLY

1. The camp director should observe the local health laws concerning camp water supply.

2. The water supply for drinking and culinary purposes should be adequate and safe and approved by local or state health departments prior to the opening of camp. When water from a public supply is carried in, clean containers should be used. Such transportation should be done under the direct supervision of a member of the camp staff. Containers so used should be used for no other purpose, should be equipped with covers that protect the lip of the container, and should be sterilized as necessary. The water should contain at least 0.1 p.p.m. of free residual chlorine or some equally effective disinfectant at the time it is drawn in camp for consumption. Containers in camp should be fully protected against contamination and equipped with spigots or some similar method for drawing off the water. The use of a common drinking cup should be prohibited. If drinking fountains are provided, these should be of sanitary design and construction.

3. Wells and springs should be so located as to avoid any chance of contamination from buildings or other sources, and should be adequately protected. Such sources should be properly encased in masonry or tile, this to extend well above the surface of the ground, and a tight covering provided. Removal of water by dipping or drawing by a bucket is prohibited. Prior to the selection of springs or the construction of wells, advice should be sought from the local health authorities.

4. Connections between approved and non-approved sources should not be permitted. If a non-approved supply is used for any purposes, it should be separated from the approved supply and should be used in such a way that use for drinking or culinary purposes will be prevented. Non-approved supplies might be used for such purposes as flushing toilets. The water supply system should be examined by a competent person to locate and eliminate any possible danger, such as back siphonage. The use of lead pipe as conducting medium is prohibited.

VI. BATHING BEACHES AND SWIMMING POOLS

1. Swimming and bathing waters should be controlled so that they are in accordance with local and state regulations. "Recommended Practice for Design, Equipment and Operation of

Swimming Pools and Other Public Bathing Places,"[1] published by the American Public Health Association, is a dependable guide. The swimming area, including the drainage area feeding the body of water used for swimming should be free of possible sources for pollution, such as overflowing cesspools, open privies, etc. The responsible health department should be called upon to assist in determining the safety of the area. For a discussion of sampling, see the reference cited above. The bottom of natural swimming areas should preferably be of sand or gravel, free from excessive mud or silt deposit or vegetation. Shores should be kept free from any litter or unsightly material.

2. *Supervision* — Every place where swimming is conducted should be under the direction and supervision, during all swimming periods, of a competent and qualified person who should require careful observance of sanitary regulations. Such person should establish an individual check-in, check-out system for all swimmers. The "buddy system" is recommended particularly for children and non-swimmers. In the case of artificial or partly artificial pools the supervising person should also be responsible for a daily record concerning the volume of new water added, the time of cleaning the pool, and the quantity of disinfectant added. Swimmers should be inspected for skin infections, open lesions, etc., and should have a cleansing shower before entering the pool. This is particularly important in the case of artificial pools, usually much smaller than natural bathing areas.

3. All camps maintaining swimming facilities should provide adequate, well kept life saving equipment consisting of a nearby unlocked boat with oars and life belts, life ring with line, grappling hooks, long pole with hooks, ropes, and like equipment instantly available and in good condition. Red Cross standards or equivalent are to be observed.

4. Instructions should be given against urinating or spitting, or washing animals in the waters of bathing beaches. Adequate toilet facilities should be available at the bathing area. Care must be exercised to prevent pollution of the area by these toilets.

VII. TOILET AND SEWAGE DISPOSAL FACILITIES

1. The toilet facilities and methods of sewage disposal should be approved by the local or state department of health. There should be provided convenient and adequate toilet facilities, so located, constructed, and maintained that they shall not be offensive to the users, becoming the breeding place for flies, nor by leakage or seepage offer a possible contamination of adjacent waters. Sewage disposal systems should not allow seepage of sewage to the surface of the ground. Defilement of camp grounds by excretions should not be permitted to occur.

2. Where privies are used the construction shall involve a pit more than 2 ft. deep. Both the shelter and the pit shall be made fly tight; self closing lids on the seats shall be provided, and clean and sanitary conditions maintained at all times. No such pit should be permitted to become filled to less than 1 ft. below the surface of the ground. Privy contents should be removed as often as necessary and disposed of in a satisfactory manner.

If temporary, the pits should be filled in when contents arise to within 2 ft. of the surface of the ground. The surface of the pit contents should be thoroughly sprayed with oil or some other heavy disinfectant before back-filling. If permanent pits are used, i.e., concrete or brick, the contents of these pits should be dumped into a public sewerage system, if possible, otherwise buried. Care should be exercised during this entire emptying process to prevent pollution from utensils used, spillage, etc.

3. Chemical toilets, making use of caustic alkali, may be found preferable to privies. The accumulated fluid should be so disposed of underground that no hazard of pollution of any water supply or of any body of water will be entailed.

4. *Since proper size and construction* is essential for the satisfactory operation of a septic tank or cesspool, a public health engineer should be consulted in the construction of sewage disposal systems of these types.

5. No privy shall be within 100 ft. of any place where food is prepared or served. No privy, cesspool or septic tank should be within 75 ft. of any lake, pond, or stream, or within 100 ft. above or in *direct* line of drainage thereto of any well or spring.

6. Separate toilets should be provided for each sex, if both are to be in camp at the same time. At least eight seats per 100 and four urinals per 100 boys additional should be provided. Since diarrheal outbreaks may occur, increasing enormously the demand for toilet facilities, the camp staff must be ready to provide additional, satisfactory improvised facilities, as needed, until the emergency has passed.

VIII. GARBAGE AND WASTE DISPOSAL

All garbage and kitchen wastes shall be deposited in covered metal receptacles which shall be regularly emptied and cleansed, and the contents burned, buried or otherwise disposed of in such a manner as not to give rise to offense or to permit access of animals or flies. Burial is the most satisfactory method of disposal under crude conditions.

During summer months garbage cans should be emptied daily and washed before return to the garbage rack. Access to the contents of garbage cans by rodents or other wild animals should be prevented. Care must be taken to prevent the garbage rack or storage area for the garbage cans from becoming an insect breeding area or a nuisance because of spillage. Emptied tin cans should be rinsed to remove any possible food for insects, and then crushed to prevent the accumulation of water that might serve as a mosquito breeding accumulation.

IX. FOOD AND FOOD HANDLING

Adequate provision should be made for the sanitary storage, handling, protection, and service of all food supplies. Refrigeration for perishable products should be provided. Cooks and all food handlers should keep clean and wear clean clothing. No food handler, when ill, should work about the kitchen, except as permitted by a physician. In the case of food handlers, it is suggested that a health examination be given by the camp physician or that a very specific questionnaire be prepared so that assurance can be had that a thorough and meaningful physical examination has been given. Persons who have ever had typhoid fever should not be employed in the kitchen or handle food or food materials until it has been definitely determined by appropriate tests that such persons are not typhoid carriers.

X. MILK AND CREAM

Milk and cream and soft drinks supplied to camps should be produced and handled in accordance with the regulations governing, and should conform to the requirements respecting composition, labeling, and bacteria content. Only pasteurized milk and cream should be used.

XI. MEDICAL AND NURSING CARE

At all regularly established camps there should be:

1. A definite written arrangement by the camp management with a physician licensed to practice in the state to be on call at all times for medical service and to supervise first aid and nursing service in the camp.

2. Someone, either the camp manager or an employee designated for this purpose, in the camp at all times, who is especially trained in first aid service.

3. Adequate provision for first aid attention on all trips out of camp.

4. Standing orders issued by the physician to the person responsible for first aid service to be followed in the absence of the physician.

5. If at all possible, a telephone in camp, or available within 10 minutes' travel time therefrom.

6. Some means of quick transportation in case of emergency.

7. In all camps operated for children who are not physically normal, or at which the total number of persons, including campers, employees, and administrators, is at any time greater than 75, there should be employed: (1) a registered professional nurse, (2) a medical student who has satisfactorily completed 2 years in medical school approved by the state board of registration in medicine, or (3) a physician in residence. For the purpose of this section and of section 3, "registered professional nurse" should mean one who has qualified for such service under the law of the state, and at camps in which this service is in lieu of (2) or (3), above, she should be so qualified.

XII. COMMUNICABLE DISEASES TO BE REPORTED

All cases of communicable diseases occurring in camp should be immediately reported in accordance with regulations of the local health office. Such report in accordance with local or state regulations should include the name and home address of any individual in the camp known to have or suspected of having such disease. The method of isolation should be one approved by the local health officer. The person in charge should not allow the patient to leave or to be removed without permission of the health officer.

XIII. OTHER ILLNESSES

Whenever there should occur in camp any outbreak of suspected food poisoning or an unusual prevalence of any illness in which diarrhea, fever, sore throat, vomiting, or jaundice is a prominent symptom, it should be the duty of the person in charge of the camp to report immediately the existence of such an outbreak or disease prevalence to the local health authorities.

XIV. HEALTH EXAMINATION

The pre-camp examination, given by a physician, should ideally be made far enough in advance of the camp season so the remediable defects found, and necessary immunizing, can be taken care of before the opening date. This should always include smallpox, tetanus, and diphtheria protection and other indicated immunizations depending upon the location of the camp. In addition to this, there should be a brief examination shortly after arrival at camp by a registered nurse or physician, for early symptoms of contagion.

XV. HEALTH EXAMINATION OF STAFF

All members of the staff should have a complete health examination before camp opens. They should understand and be prepared to accept the responsibility of the physician or the nurse in relation to their own health. It is recommended that stool specimens of all food handlers be examined. Many state health departments will make these examinations without cost.

XVI. INFIRMARY

The camp administration is responsible for provision for adequate and safe infirmary facilities, including isolation. It is essential that the physician or nurse be sure these facilities are available prior to the opening of camp. Where quarters have not been provided for an infirmary, it is suggested that space be arranged apart from the living quarters,

and preferably in quiet surroundings. The number of beds needed will depend upon the number of campers, their age and sex, duration of stay, and whether the camp is serving handicapped children. One bed to 15 campers is suggested as a minimum. Furniture should be simple, easily cleaned, and consist only of the necessary items.

BASIC EQUIPMENT AND SUPPLIES FOR AN INFIRMARY

3 enamel wash basins
1 irrigating can and assorted tips
2 kidney basins (curved)
2 bed pans
sterilizer for boiling equipment
2 bulb syringes
2 hot water bottles
2 large rubber sheets
2 small rubber sheets
1 tourniquet
paper cups
wooden tongue depressors
wooden applicators
1", 2", and 3" bandages
triangular bandage
½", 1", and 2" adhesive (water proof)
3" x 3" sterile gauze compresses
band aids
sanitary pads and belts
yellow and white soap
sterile absorbent cotton
1 hemostat
1 nail scissors
2 bandage scissors (one large—one small)
1 scalpel with blades
½ dozen bulb pipettes
½ dozen test tubes
glass slides
1 thumb forceps (toothed)
1 tweezers (needle point)
4 medicine glasses
2 medicine droppers
Luers syringes—1 c.c. and 2 c.c.
20 c.c. syringe for convalescent serum
hypo needles (different sizes)
suture material and suture needles
needles (for removal of splinters)
safety pins
alcohol lamp
splints (different sizes)
flashlight
dishes, eating utensils, etc.
necessary linen
height and weight scale
American Red Cross First Aid textbook
alcohol 70%
tincture of green soap
tincture of iodine 3½% and/or 2%
mineral oil
milk of magnesia
Aspirin (Gr. V)
sodium bicarbonate tablets (Gr. V)
calamine lotion with phenol 1%
ampules of tincture of iodine
aromatic spirits of ammonia
boric acid crystals
magnesium sulfate crystals
paregoric
phenobarbital tablets (Gr. ½)
ointment for burns
5% sulfathiazole ointment (ophthalmic)
yellow oxide of mercury 1% (ophthalmic)
boric acid ointment
inhalation compound (Tr. benzoin base)
larkspur or kerosene
ammoniated mercury ointment 5%
adrenalin ampules
cocoa butter
talcum powder
cold cream
salt
vaseline
penicillin and sulfa preparations on suggestion of physician

Community Organization for Health Education*

Public Health Education Section

THIS committee is successor to the old Committee on Community Organization for Health Education which went out of existence after publishing a report under the same title in 1941, based upon a study of communities which had developed particularly successful organization, between public health, school health, and voluntary health agencies. That report had three reprintings and was distributed in the number of 15,000 copies. It had not seemed wise to seek further reprints of such an old report and the present committee was appointed in 1946, to explore the desirability of further studies, reports, or Section activities in this field.

About 100 members of the Section indicated on post cards that they preferred to work with this committee. There was a discussion of the whole problem at the 1947 A.P.H.A. meeting. The attached questionnaire was sent to the whole committee in April, 1948. The replies were summarized and reviewed by the Chairman with the assistance of Vivian Drenckhahn and Aubrey Mallach. The following report summarizes the thinking of the committee.

I. The following types of community organization were mentioned in committee discussions and on questionnaires. (The phraseology here used is that of a formal paper presented by the Chairman at the 1948 A.P.H.A. meeting on "Health Education and Community Organization.")

Local level:

1. A school health council in which professional people in health and in education join with lay people in planning for health promotion, but restrict their activities to problems of school health.

2. The health council or health education committee of official agencies through which departments of local government, concerned with health, coördinate their health education and sometimes other health activities.

3. The health council of voluntary and official health agencies, established either independently or as a health division of a council of social agencies where official and voluntary health activities are planned and coördinated in the absence of the groups which are consumers of health service.

4. The health council representing official and nonofficial health agencies and also other civic or health-consumer groups, who work together in planning and developing health activities.

5. The health council made up of lay individuals and lay organizations only, which plan and promote health activities with the aid of official and unofficial health groups, bringing in professional consultants to aid in their discussions as necessary.

6. Welfare councils of lay and professional groups similar in composition to group 4, but organized to consider all problems related to the public welfare.

State level:

1. A state health council representing only the official agencies.

2. A state health council representing both official and voluntary state-wide health agencies.

3. A state health council representing official and voluntary health agencies together with lay and civic groups, the scope of which tends to broaden.

National level:

1. National conferences of official health agencies, like the Surgeon General's Conference and the Conferences of State and Provincial Health Officers.

* Report of the Committee.
COMMITTEE ON HEALTH EDUCATION AND COMMUNITY ORGANIZATION.
Organized 1946.

2. The National Health Council, made up primarily of the national voluntary health agencies.

3. The National Conference for Coöperation in Health Education, made up of national official and voluntary groups in health and in education, and concerned only with health education problems.

4. The National Committee of Health Council Executives, made up of the executive officers of local health councils, for a consideration of council programs and methods.

5. The occasional conferences of specialists and representative groups called by the national government, like the recent National Health Assembly and the various White House Conferences on specific health problems.

II. The committee suggested several references to books and papers on the subject of Community Organization. The most pertinent and helpful were:

1. American Public Health Association. *Community Organization for Health Education.* New York, 1790 Broadway, 1941, 120 pp. (This report is now out of print, but it has been widely distributed.

2. Federal Security Agency. *The Nation's Health—A Ten Year Program.* Washington, D. C., 1948. (pp. 179–186 deal with Community and State Planning. It is expected that a special publication will be issued on this subject.)

3. National Health Council. *Stepping Stones to Health Councils,* 1948, 30 pp.

4. Association for the Study of Community Organization. *Community Organization,* 60 Farnsworth Avenue, Detroit 2, Mich. 1947. 28 pp. (25 cents.)

5. Iowa Community Development Workshop. *Guides for Building Communities.* Des Moines Community Development Committee, Iowa Council for Better Education, 415 Shops Building, Des Moines, Iowa, 1947. (Mimeo. 31 pp. 25 cents.)

6. Washington State Department of Health. *Health Councils for Washington.* Smith Tower, Seattle, Wash., 1947. 11 pp.

7. Michigan Council on Adult Education. *Organizing a Community Council.* Lansing, Mich. Superintendent of Public Instruction, 1944. 22 pp.

III. Several problems were suggested for committee discussion and considered, namely:

a. The relationships of official agencies
b. The desirable nature and extent of lay participation
c. The functions of the health educator in community organization
d. How to organize a community
e. The coördination of voluntary health agencies
f. Hospital participation
g. Education of the public concerning existing agencies
h. How to enlist lay interest
i. The evaluation of health education in the community
j. The relationships of the County Medical Society
k. What are the training opportunities in community organization in schools and colleges
l. How are leaders found
m. How is group interest maintained

IV. The committee mentioned several projects and studies in Community Organization which are under way. However, field contacts and the discussions at the National Health Assembly showed that the projects named by the committee are only a few of those actually under way. For that reason this partial list is not included in the report.

V. Several possible activities were suggested for the committee. Many of these activities, however, are being carried forward by some group at present, as indicated below.

The Committee suggested:

a. The development of an evaluation schedule for Community Organization. (Community Chests and Councils is developing such a schedule and the National Tuberculosis Association is setting up a self-evaluation schedule for Tuberculosis Associations. This schedule, however, includes community relationships.)

b. The development of a Newsletter on Community Organization. (The National Health Council will issue a monthly bulletin, dealing largely with this subject.)

c. Recommendation from the committee to universities that they provide refresher courses for health educators. (This would hardly seem an appropriate function for the Section committee.)

d. A survey of the instruction which health educators now receive and should receive in professional schools regarding Community Organization. (This assignment would seem more appropriate for a new Section committee concerned with this single project and with a membership selected in relation to the project.)

e. A survey of existing community organization with the preparation of community case studies in this field along the lines of the published report of the old committee. (The National Health Assembly reviewed several community projects of this type, and will presumably publish reports concerning them. Other similar projects are being reported in the literature. There is now an Association for the Study of Community Organization. The committee does not believe it desirable to reprint the old report, although it has been very valuable. On the basis of the facts just cited, it seems desirable to await the publication of the reports of the National Health Assembly in order to see whether that together with currently appearing articles meet the need for studying and reporting progress in community organization for health.)

RECOMMENDATIONS

It is recommended:

1. That this committee, which has explored the situation, be discontinued at this time; but that the Section consider one year hence the creation of a committee to undertake a survey and case studies, if enough is not being done in this direction outside the Section.

2. That the Section appoint a committee to study present and desirable instruction in community organization as a part of the training of Community Health Educators.

3. (This recommendation comes from the discussion on community organization by the committee at the 1948 A.P.H.A. meeting as well as being reflected in the correspondence with the committee itself.) That an opportunity for a discussion on health education in relation to Community Organization be provided by the Section at the next annual meeting of the A.P.H.A.

C. E. TURNER, DR.P.H., 120 Broadway, New York, N. Y., *Chairman*

(This report was presented orally at the Section meeting in Boston, November 11, 1948.)

QUESTIONNAIRE

April 5, 1948

To: A.P.H.A. Committee on Community Organization in Health Education

From: C. E. Turner, Chairman
120 Broadway, New York, N. Y.

You will recall that the committee voted at Atlantic City to seek this year to define the problem, to find out what agencies are now at work on problems of community organization and to suggest a specific program for the committee. As a responsible member of the committee, you are asked to contribute your thinking on the following points and to send your reply to the Chairman *not later than one week* from the day you receive this memo.

1. What types of community organization exist which are concerned with health education? The following were suggested:
   (1) A Health Education Committee of health agencies.
   (2) A Health Council of Voluntary and Official Health Agencies.
   (3) A Community Health Council representing both lay and professional groups.
   (4) A Council of Social Agencies (with a health committee) to consider problems of welfare as well as health.
   (5) A Community Council of lay and professional groups to consider all problems related to welfare of the people.

   Please change titles in the above list if needed.

   Will you add any others?

   Will you define them?

2. (a) What agencies on the national level are concerned with community organization in any form?
   (b) What published statements or papers do you know of dealing with health education in relation to community organization?
   (c) What studies in community organization do you know of which are under way?

3. Please suggest five members of this committee to serve as an Executive Committee.

4. Please list below the problems of community organization in relation to health education which you think the committee should consider.

   (Some that have been suggested are (1) The relation of official agencies; (2) Lay participation; (3) The function of the health educator. What are the others?)

5. List the things you think the committee should undertake. (Give your suggestions for committee procedure from this point.)

6. What states, cities, towns, counties or communities in the U. S. have done the best job in community organization for health and health education? (Give the names of responsible persons in each case.)

Planning for Health Education*

Public Health Education Section

THE Committee on Planning for Health Education is an outgrowth of a Committee on Post-war Planning, which was appointed following a meeting of the American Public Health Association in 1945. The first report of the committee brought to the Section the areas of content in which planning would need to take place following the war. To implement this overall program of content, as it was given in 1946, the committee presented to the Section in 1947 an estimate of the number of personnel that would be needed to carry out an adequate program over the nation. This estimate was based first on a uniform standard of one health educator to each local health department, proposed by the Committee on Local Health Units for the Nation, and one additional health educator for each 100,000 personnel in jurisdictions serving over that number, and estimates submitted by as many of the states as were willing to project plans for carrying on their health education program.

The committee is very much gratified to see that some of its proposals are being accepted by the profession and are appearing in printed statements by other groups in the public health profession. For example, the new Report of the Committee on Professional Education on the *Qualifications of Community Health Educators* summarizes the estimates of personnel as given by the committee report of 1947. Also, in the Report to the President on *The Nation's Health—A Ten Year Program*† will be found the following paragraphs:

> An extension service for health, comprising health educators attached to local, State, and Federal health agencies, could perform invaluable service in helping communities and States to organize citizen health councils. Such a service, I believe, would do much to assure the success of the national program for better health and to help communities make good their deficiencies in resources and coördinate their health services.
>
> As a Nation we would probably need one health educator for every 50,000 population—a total of some 2,800 workers. Voluntary agencies and schools will need hundreds more. We should be able to train enough workers for effective extension services in considerably less than the next 10 years if we move promptly and forcefully toward this end.

In addition, the material on local health units indicates that the following personnel are essential to effective local public health organization:

1 full-time medical health officer per unit
1 additional full-time public health physician for each 50,000 population
1 full-time nurse for each 2,000 to 5,000 population
1 sanitarian for each 15,000 population
1 health educator for each 50,000 population
1 clerical worker for each 15,000 population

Additional professional and technical workers for each of the special programs, in the ratio of one per 50,000 population, except that dentists, dental hygienists, veterinarians, and laboratory workers would be employed full time only in units that served at least 150,000 persons.

The acceptance of these estimates of the committee are gratifying, and encourages us to continue in our work of developing material that may be useful

---

* Report of the Committee.
COMMITTEE ON PUBLIC HEALTH EDUCATION PLANNING.
Organized 1945 as Post-war Planning in Public Health Education.

† By Oscar R. Ewing, Federal Security Administrator.

in pushing forward satisfactory goals in public health education.

In addition to the preparation of these estimates, in 1947, the committee explored new areas in which planning was needed. As a result of that exploration, six new subcommittees were formulated to work on the several areas considered important. The first subcommittee was asked to obtain data from the 19 states that had not reported at the time of the 1947 Annual Meeting of the Association, and thus make the final estimates more realistic. The second was to explore the types of personnel that are needed in various population units and administrative groups. The third was a committee on the philosophy of health education. It was asked to prepare answers to such questions as these: "Toward what are we moving in health education? Is our conception too narrow? How can we plan for future needs in the broad realm of human welfare?" The fourth was to study what types of personality traits are needed in health educators. The fifth was asked to propose a minimum salary schedule for various health education personnel. The sixth was to develop proposals that would aid in the maintenance of a high caliber of personnel in the field, and was asked to consider such problems as salary, recruitment, undergraduate programs, and how can the health educator's job be made more satisfying.

During the year, these committees have been busy—some more energetically than others.

There is published elsewhere in this issue, the first report of the Subcommittee on Salary for Health Education Personnel, which has been accepted and adopted by the committee. We recommend its adoption by the Section Council. The Subcommittee on Personnel has developed one questionnaire and is in the process of revising that questionnaire in order to send it to official health agencies, official education agencies and voluntary health agencies. It is believed that the material from this questionnaire will give us valuable data in understanding our future needs in health education.

The report of the subcommittee, on the types of personality that health educators should have, submitted a report. The committee did not find its actions fruitful, and it is recommended by the overall committee that this subcommittee be abolished, with thanks, for their exploratory efforts.

The committee on securing further data from the states was unsuccessful in obtaining replies from any other than the 29 states from which we had already heard. Therefore, this committee has been discharged with thanks.

The Committee on General Philosophy has done some careful thinking but is not ready to report. It is hoped that they can continue during the coming year, and that a very substantial report may be obtained from them in 1949.

Following these committee reports, those present at the committee's meeting were asked to explore additional areas of planning. Four new areas were suggested. They are:

1. What is being done in organized field training for apprentices, externs, aides, etc.? What is desirable in this field, and how can field work be offered when schools are in session?
2. Evaluation of health education
3. How to interpret what health educators do, to the public health staff and to others
4. Standardization of job nomenclature and job descriptions for each named job

It is proposed to set up four new subcommittees to work on these new subject areas. The members who were present at the session were asked to indicate on which of these subcommittees they would like to work, and to volunteer if they were interested. Over half of those present volunteered to serve on one or more of the committees.

It is the recommendation of the Committee on Planning for Health Educa-

tion that it be permitted to continue its work along the lines indicated in this report, and that the membership be informed of the areas of planning in which the committee is active. It is also recommended that the membership be invited to participate in drawing up the reports for 1949 on the areas of planning that have been suggested.

The Chairman wishes to record to the Section Council his appreciation for the splendid work that has been carried on by a large number of the members of the Section.

MAYHEW DERRYBERRY, PH.D.,
U. S. Public Health Service,
Washington, D. C., *Chairman*

Proposed Levels of Recommended Starting Salaries for Six Grades of Positions for Community Health Educators*

Public Health Education Section

THE Subcommittee on Salary for Health Education Personnel is a subdivision of the Committee on Health Education Planning of the Public Health Education Section, American Public Health Association. The Subcommittee was created at the 75th Annual Meeting in Atlantic City, N. J., October 7, 1947.

Members of the subcommittee who have served during the reporting year, are: Mayhew Derryberry, Ph.D., Washington, D. C.; Catherine Dees Hidy, M.P.H., Little Rock, Ark.; Rosemary M. Kent, Chapel Hill, N. C.; Edith R. Lindly, M.P.H., Fresno, Calif.; S. Elizabeth Lovell, M.S.P.H., Chapel Hill, N. C.; and Alfred K. George, M.D., Cincinnati, Ohio, *Chairman.*

The subcommittee, in an effort to correlate efficiently its activities with the work done by other A.P.H.A. committees in related fields, has frequently been in contact with the Committee on Planning for Health Education (*Chairman:* Mayhew Derryberry, Ph.D.), the Subcommittee on Salary Study of the Committee on Professional Education (*Chairman:* William R. Willard, M.D.), and the Subcommittee on Investigation of Types of Health Education Personnel (*Chairman:* William Griffiths). The fine coöperation of these committees has been stimulating and very helpful to the activities of the Subcommittee on Salary for Health Education Personnel.

This report deals with the general salary situation concerning community health educators and especially with the consideration and fixation of appropriate levels of starting salaries. The report contains various pertinent recommendations and in particular it includes the tentative draft of a minimum salary scale for six grades of positions for community health educators. Classifications and qualifications to be required for these positions are indicated accordingly.

The report does not include considerations and suggestions relative to the salary situation of school health educators nor of various specialists working in the field of health education as writers, editors, public relations officers, research analysts, librarians, audio-visual specialists, exhibit designers and technicians, photographers, and others. However, the question of what should be the range of salary for health education personnel of these types not covered in this report is certainly of great concern to the Subcommittee on Salary for Health Education Personnel. Therefore, it seems advisable to discuss this matter and report on it in the near future.

---

* Revised Report.

SUBCOMMITTEE ON SALARY FOR HEALTH EDUCATION PERSONNEL OF THE COMMITTEE ON HEALTH EDUCATION PLANNING.

Organized 1947.

THE EXISTING SALARY SITUATION AND THE IMPORTANCE OF APPROPRIATE SALARIES

The existing salary situation as it concerns public health workers and in particular public health education personnel has been reviewed carefully. In this respect, information transmitted by William R. Willard, M.D., of the Subcommittee on Salary Study of the A.P.H.A. Committee on Professional Education (William P. Shepard, M.D., *Chairman*) was highly beneficial. Another valuable contribution was made by Robert O. Yoho who circulated a questionnaire requesting the salaries of presently employed health educators. A third instructive source of knowledge was the survey on "Salaries of State Public Health Workers," published by the Federal Security Agency, U. S. Public Health Service, in February, 1948. Sincere thanks are expressed to the *American Journal of Public Health* and its esteemed Editor, Professor C.-E. A. Winslow for the publication of excellently selected informative material, presented so thoughtfully and efficiently in the *Journal's* section "Clearing House on Public Health Salary Information."

Without doubt, most salary surveys and salary schemes of more recent dates, with the possible exception of the federal payment system and a few others, indicate clearly the considerable underpayment of health educators. Apparently, it cannot be stated ardently enough again and again that careers in public health, including the field of public health education, would be much more attractive to many able individuals if these men and women would receive really adequate salaries.

In order to change the present detrimental situation and in an effort to explain the conditions so that things might be better understood by the public, it seems appropriate and timely to use some additional comparative methods of presentation. Salaries paid to health educators and to other public health officials should be compared with selected salary and wage scales for members of other professions and occupations including labor, without being too critical even of seemingly very generous wage scales. Such an endeavor would be of great benefit to public health educators as well as to other public health groups in their highly justified struggle for much needed improvement in their economic conditions.

THE FIXATION OF APPROPRIATE SALARIES

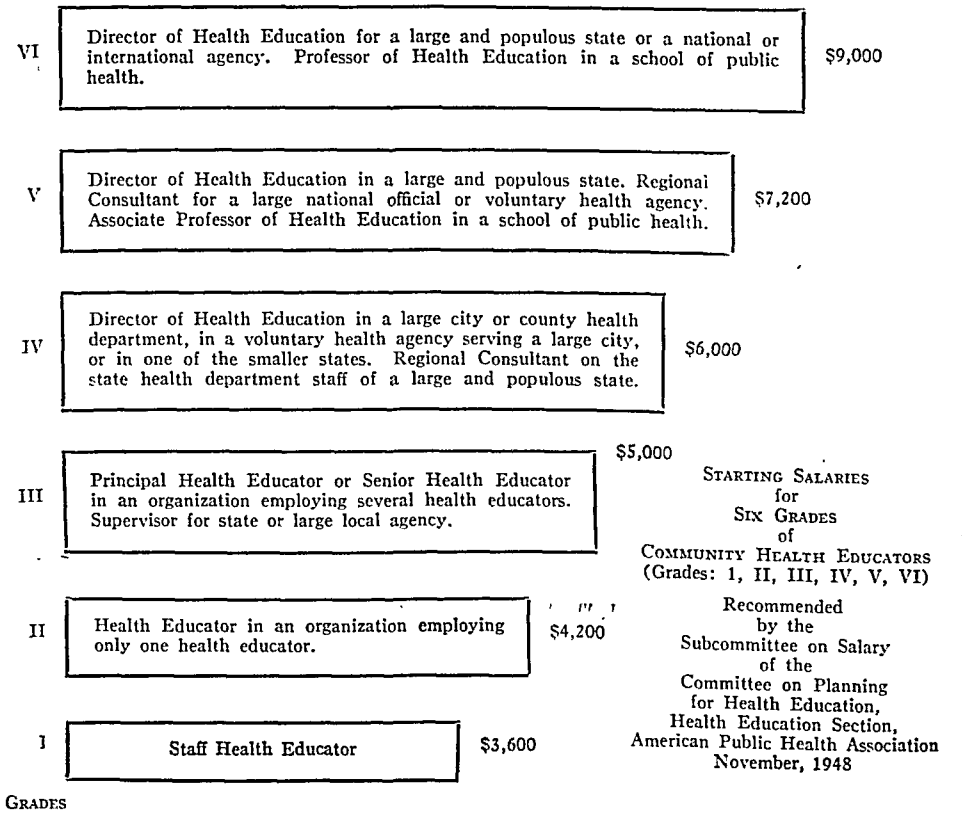
The fixation of appropriate salaries depends upon many factors, such as: general salary policies of the agencies concerned; the structure of general and special salary schemes; salary levels of certain other employees, in particular various public health workers, teachers, and social workers; the financial ability of agencies employing public health personnel; the power of taxation and the degree of taxation; the stability and the purchasing power of the currency; the general price and rent situation; and, in addition to a number of other factors, the public opinion acting as a forceful power if molded on the basis of accurate and skillfully imparted information of the public.

As to the question of remuneration, it might be generally advisable not to speak of salary increases at all but instead of salary adjustments as necessitated mainly by the effect of the formidable decrease of the purchasing power of the dollar and the effect of taxation on the amount of the "take home pay."

It is beyond the scope of this report to present complete model salary schemes covering such items as ascending salary ranges, salary increments, promotional increases, travel allowances, vacations with salary, retirement plans, etc. This report aims to show that, in order to combat underpayment, careful consid-

eration must be given in particular to the determination and specification of suitable levels of minimum starting salaries for the various groups of community health educators. In this connection it might be stated that, judged from a general as well as an individual standpoint, the most important salary level is that of the minimum starting salary of the beginner.

Considering the fact that the average weekly (40 hour) income of the 13,200,000 production workers in the nation's manufacturing plants increased to about $54 in August, 1948, and in view of wages for bricklayers amounting up to $3.65 per hour in September, 1948, it seems inadvisable and detrimental to the group to recommend an amount less than $3,600 as minimum starting salary for community health educators with M.P.S. degrees.



RECOMMENDATIONS OF SIX GRADES OF POSITIONS FOR COMMUNITY HEALTH EDUCATORS AND OF CORRESPONDING LEVELS OF MINIMUM STARTING SALARIES

Six grades of positions for community health educators are suggested in this report: Grades I, II, III, IV, V, and VI.

The corresponding minimum starting salaries are proposed at the following levels: $3,600 for Grade I, $4,200 for Grade II, $5,000 for Grade III, $6,000 for Grade IV, $7,200 for Grade V, and $9,000 for Grade VI.

Starting salaries above $9,000 should be considered for eminent positions of very heavy responsibility and for leading positions in areas of high-cost living conditions. Classifications including accurate job descriptions, corresponding grades of positions, and recommended starting salaries are indicated in chart.

CHART I

RECOMMENDED QUALIFICATION REQUIREMENTS FOR SIX GRADES OF COMMUNITY HEALTH EDUCATORS (GRADES I, II, III, IV, V, AND VI)

GRADE I: Graduation from an accredited school of public health with a major in health education; no experience since graduation.

GRADE II: Graduation from an accredited school of public health with a major in health education and at least 1 year of experience as a health educator.

GRADE III: Basic qualifications as stated above and at least 3 years of experience as a health educator.

GRADE IV: Basic qualifications as stated above and not less than 5 years of experience as a health educator.

GRADE V: Basic qualifications as stated above, 6 to 10 years of experience as a health educator and as an administrator or as a supervisor of a health education program for a large population group.

GRADE VI: Basic qualifications as required for Grade V but not less than 10 years of outstanding and successful experience in local and state or national organizations and/or teaching experience in health education acquired preferably in a school of public health.

SPECIAL PROVISIONS FOR THE SUBSTITUTION OF QUALIFICATION REQUIREMENTS

It is obvious that special provisions relative to qualification and classification must be made in favor of those men and women who have been active in health education successfully for years without possessing graduation requirements that are proposed for respective positions at this time. In order to cover the qualification of individuals as identified above, it is considered necessary to incorporate into the classification and salary scheme a special mandatory clause, as follows:

"Graduation from an accredited school of public health with a major in health education is not held a required qualification for persons who have already been active in the field of health education for years (health education 'pioneers')."

Numerous individuals who are well known in health education, and among them many who are prominent in this field, possess Master degrees and other than degrees with a major in health education and/or Doctor degrees of various kinds. In order that there might be no doubt about the qualification and classification of these persons, the following special clause as an integral part of the proposed classification and salary scheme seems necessary:

"Master degrees other than degrees with a major in health education, and Doctor degrees as degrees of Ph.D., Ed.D., Dr.P.H., M.D., D.D.S., D.V.M., Dr.Eng., and Sc.D. are considered full qualifications for persons with additional experience and reputation in the field of health education."

RECOMMENDED MINIMUM STARTING SALARIES FOR ASSISTANTS (AIDES, APPRENTICES) IN COMMUNITY HEALTH EDUCATION

There are a number of recent graduates with Bachelor degrees in health education who are working in the field of community health education, individuals who are expected to serve more or less in the capacity of assistants, aides or apprentices in community health education rather than as full-fieldged workers with independent responsibility for the program in health education. Generally, minimum starting salaries of $3,000 for this group seem reasonable.

ACKNOWLEDGMENT—The Chairman of the Subcommittee on Salary for Health Education Personnel wishes to express his sincere appreciation and thanks for the excellent cooperation and support given him by the members of his committee.

ALFRED K. GEORGE, M.D., University of Cincinnati, College of Medicine, Department of Preventive Medicine, Cincinnati, Ohio, *Chairman*

Public Health Films*

Public Health Education Section

DURING the past year a Subcommittee of the Committee on Public Health Films (Public Health Education Section) has been exploring needs in the health field with a view to suggesting practical solutions.

Examination of the field indicates the lack of any central intelligence to assemble and disseminate information on health films. It has shown the need now for the establishment of a National Service or Agency with sufficient funds, personnel, and prestige to play an effective part in promoting the production of better health films and a better use of health films.

Specifically the subcommittee recommends:

1. The establishment of a beginning program of health film reviews in the American Journal of Public Health for which detailed recommendations have been prepared. This project is approved to be started as promptly as possible and without waiting for the establishment of Section II of this program.
2. The establishment of a Health Film information and coördination service under the auspices of a National Health Agency, which would:
   a. Establish a clearing house for all health film projects.
   b. Collect and disseminate information on health films.
   c. Promote the publication of health film catalogs.
   d. Promote the wider appreciation of the movies as an important means of education and encourage research in this field.
   e. Promote the establishment of reference film libraries and information centers on a regional basis.
   f. In general, keep in touch with the needs of the health film field, make these needs articulate and sponsor sound health film development.

* Report of the Chairman.
COMMITTEE ON PUBLIC HEALTH FILMS.
Organized 1946. Published report: *Year Book*, 1947–1948.
Approved by the Public Health Education Section.

School Health Section*

DURING the past year your officers have given particular thought to ways of making the Section better serve the needs of its members. We believe that the annual meetings need to be augmented by some plan of year around working on problems and sharing of experiences which will reach every member, not just those fortunate enough to get to an annual meeting. Such a plan is not easy to work out. We have over 300 members scattered across Continental United States, the territories, and in other countries; and our members consist of a number of professions engaged in every aspect of service to children of school age. On the other hand, we have a community of interest and an eagerness to improve our understanding and skills which we believe will serve to overcome the difficulties. As a step toward better understanding of our needs, I have done some analyzing of the membership to find out what kind of people we are professionally, what kinds of jobs we have in school health, where we work, and who employs us.

MEMBERSHIP OF THE SECTION

There are now some 334 members in the School Health Section, an increase of about 50 in the past year. We have members in 37 states, the District of Columbia, Alaska, Hawaii, Puerto Rico, and also in Canada, Holland, China, and India. The distribution of the membership shows a concentration in the more populous states as would be expected, but 11 of our states have no members at all and 15 states have only one or two members. This would seem to indicate that large sections of the country are being less influenced by the work of the Section than we would like. We have 46 Fellows. Their numbers are too few and the distribution is too uneven to make for a really representative group from which to choose the leadership of our Section.

GEOGRAPHIC DISTRIBUTION OF MEMBERS

Largest	New York	77
	California	44
	Pennsylvania	21
	Massachusetts	17
	Illinois	14
	Ohio	14

No members in 11 states—Vermont, New Hampshire, Delaware, Alabama, Mississippi, Arkansas, New Mexico, Wyoming, North Dakota, Idaho, or Nevada.

In the states with larger number of members some attempt was made to determine the proportion of members in metropolitan and the more rural sections of the states. Of the 77 New York members, 52 are in New York City, and 26 are in upstate New York. In California, 18 are in metropolitan areas, and 26 outside the metropolitan centers. In Pennsylvania, 9 of the 21 are in Philadelphia or Pittsburgh, and the remaining 12 are elsewhere in the state. In Massachusetts and Illinois, most members are outside the metropolitan centers. In general there are somewhat more members outside metropolitan centers than in them.

The location of the Fellows is shown to be concentrated in New York and California.

TYPE OF SERVICE BEING RENDERED BY MEMBERS OF THE SECTION

Analysis was made of 296 members, on whom sufficient data are available. Thirty-eight were listed as students and

* Report of the Chairman.

others whose positions were not indicated on the membership list.

Physicians Rendering Health Services to Children of School Age Constitute the Largest Group—84, or 28 per cent—Direct Services, 66; Administration of School Health Services, 18.

Nurses Engaged in School Health—58, or 20 per cent—Includes direct service and supervision.

The two Health Service groups combined account for about 50 per cent of the membership.

Teachers—68, or 23 per cent—Of these teachers, about two-thirds are engaged in teaching in universities and colleges, and one-third are in public school systems. About two-thirds are teaching Health Education or Physical Education and Health Education combined.

Consultants—Coördinators—50, or 17 per cent—Consultants in Health Education constitute the largest single group with consultants in school health administration, school nursing, education of the physically handicapped being reported also.

Administrators—Exclusive of School Health Administration—36, or 12 per cent—These administrators are engaged in a great variety of activities and include superintendents of schools, health officers, directors of maternal and child health of state and city departments of health, state directors of physical education and administrators of voluntary health agencies.

Who employs our members?

Local School Departments		114	39%
Elementary, Secondary, and Private Health Services	78		
Cities	34		
Rural	44		
Teachers	17		
Administration	14		
Consultants	5		
State Departments of Education		12	4%
Consultants	8		
Administration	4		
Federal Government		3	
Office of Education	2		
U.S.P.H.S.	1		
Colleges and Universities		63	21%
Total Employed by Educational Institutions		181	65%
Local Health Departments		54	18%
Health Services	42		
Cities	30		
Rural	11		
Administration	11		
Consultants	1		
State Health Departments		19	7%
Consultants	14		
Administration	4		
Voluntary Health Agencies		31	
Total Employed by Health Agencies		104	35%

What may we conclude from this for our guidance in planning future work of the Section?

1. We need to increase our membership particularly in those sections of the country not now represented. This would seem particularly important as these are the more rural sections of the country where school health services are least well developed and where the need is greatest.

2. We need to increase the number of Fellows in the Section to make possible a more representative group from which the Section may choose its leadership.

3. The Section membership now is made up of persons serving in nearly all aspects of school health—health services, both direct and administration, teachers, consultants and in the general fields of health and school administration, and in many important voluntary health agencies. We do not in this Section have engineers or others primarily concerned with school environment, an important field, and we have far too few teachers and administrators in the elementary and secondary fields. With the ever increasing recognition of the important rôle in all aspects of school health played by the teachers, it is clear that we should have more of them in our Section and would welcome them.

4. A significant fact is that local schools employ more of our members than any other agency. In program planning and selection of leadership in the Section, this should be borne in mind.

5. For those specialists who have important contributions to make to the improvement of the school health program, such as those in the fields of rheu-

matic fever, epilepsy, auditory and visual defects, and other handicapping conditions, dental health, nutrition, emotional health, and social work, we need to look to other Sections in the A.P.H.A. and to groups outside the Association for help.

One of the fine things about being a part of a great organization such as the A.P.H.A.—with its wealth of membership in all the health fields—is that we may call upon them to help us solve our problems. Every Section has a contribution to make to the field of School Health. On the other hand, we have an opportunity and an obligation to influence the thinking of those in the other Sections—to keep them abreast of modern thought and developments and special problems in our field. During this past year, our Legislative Committee, of which Dr. Baumgartner is chairman, has been active. She will report to you. Our excellent Secretary, Sol Lifson has kept you informed of developments through the newsletter. The program of this annual meeting was arranged by him to deal with the special interests and problems which you indicated in your responses to his newsletter request. On Monday evening, your Section Council met to consider ways of making the Section more helpful to all our members on a year round basis. Authorizations were given for two working committees. One, a committee to study text materials used by schools in the health fields such as general science, home economics, hygiene, physical education, and family life. It was specified that this committee be so organized as to involve as much of the Section membership as possible.

It was also authorized that the Section set up a joint committee with one from the American Association of Health, Physical Education and Recreation, to help publishers clear the health content of textbooks to be used in the schools.

The second committee authorized will make a study of Health Service Records and statistics including methods of collecting the kind of data, which will be of value in evaluating those services and conducting field tests. Other action taken by the Council was authorizing a joint committee with the American Association of Health, Physical Education and Recreation to evaluate the School Health Materials submitted from all parts of the country in connection with the Health Exhibit. The Section owes a very special debt of gratitude to Miss Marjorie Craig for the outstanding job she has done in making this material available at this meeting.

Our Section was authorized to send a letter to the Executive Board requesting appropriate action on the part of the A.P.H.A. in urging the Federal Security Administrator to call a National Conference on School Health as recommended by the Committee of the National Health Assembly.

At the Section Council meeting, two resolutions were formed for submission to the Resolutions Committee.

JESSIE M. BIERMAN, M.D., University of California, School of Public Health, Berkeley, Calif.. *Chairman*

Membership and Directory

Statistics Section

SINCE the last annual meeting, the committee has, with the coöperation of key people in each state, compiled a *Directory of Public Health Statisticians*. This *Directory* was published in October and mailed to all members of the Statistics Section.

The new *Directory* contains 1,313 names as compared with 885 included in the third edition of the *Vital Statistics Directory* published in 1945. Included are members of the American Public Health Association as well as non-members.

Letters were sent to 680 non-members listed in the *Directory of Public Health Statisticians* and 43 paid applications for membership in the American Public Health Association were received to date. Other efforts to recruit new members were made by sending invitations to individuals on the roster of a professional organization and this resulted in 30 paid applications.

Although there was a significant number of lapsed memberships by the middle of the year, the recruitment program has brought the membership of the Statistics Section to the highest point in its history. On November 1, 1948, the membership of the Section totaled 464, of which 392 were members and 72 were Fellows. On September 1, 1947, the membership total was 410, 342 members and 68 Fellows.

The total membership of the Statistics Section ranked 10th among the Association's 12 Sections in 1947 but it has now moved up to 8th place in the rank order.

Opportunities in Statistical Work*

Statistics Section

THE purpose of the Committee on Opportunities in Statistical Work and a plan for its activities were stated in the report submitted by the Committee to the Vital Statistics Section of the American Public Health Association on October 6, 1947.

A meeting of the committee was held in New York City on April 9 and 10, 1948, to plan in more detail the work of the committee. A report of this meeting follows:

REPORT OF MEETING IN NEW YORK, APRIL 9–10, 1948

Full membership of the committee was present: Ellen W. Jones, *Chairman,* Dr. Paul M. Densen, and Dr. Margaret Martin. In addition, two invited guests joined the group in the afternoon of the 9th for a discussion of recruitment of and field training for potential statisticians. The guests were: Dr. E. C. Hammond, Statistician, American Cancer Society; and Marjorie Bellows, Statistician, American Heart Association.

The major business of the meeting was concerned with the preparation of a pamphlet on careers in public health statistics. It was agreed that the pamphlet should be inspirational in tone and should be worded so as to be useful for recruiting personnel in universities, colleges, and, possibly some senior high schools. It should contain very definite information, however, on what kinds of jobs exist, where they are and the general range of salaries available for positions at various levels of responsibility. The pamphlet should direct the reader to the proper sources for obtaining specific information on these subjects. In addition, the committee felt that it would be desirable to include a statement indicating the educational qualifications needed by individuals wishing to begin a career in the field of public health statistics. Specific requirements could not be given in view of the present lack of uniformity in specifications for jobs in the various official and private agencies employing statisticians. At the same time, the pamphlet should set forth the important components of undergraduate training, and the importance of obtaining practical field experience before taking graduate training. These recommendations should, of course, be in line with those of the Subcommittee on Educational Qualifications of Personnel in Vital Statistics and Vital Records of the Committee on Professional Education.

Other subjects discussed in connection with the pamphlet were distribution and financing. Channels of distributions which were discussed briefly were as follows. Undoubtedly others should be considered also.

State health departments
Federal Civil Service
State civil service systems
Teachers of statistics, mathematics, and the social sciences
"Deans of Students" or "Deans of Junior Colleges" in colleges and universities
Libraries in colleges and universities
Vocational guidance officers in schools
U. S. Office of Education

At the time of this meeting, the com-

* Report of the Committee.
COMMITTEE ON OPPORTUNITIES IN STATISTICAL WORK.
Organized 1946.

mittee was advised that funds available through the Committee on Professional Education, which is publishing the entire series of vocational pamphlets, were extremely limited; and if anything more ambitious than a four page leaflet, without illustrations, were desired, then funds should be sought elsewhere. After considerable discussion of the aims of the Statistics Section in publishing the pamphlet, there was some indication that one of the voluntary agencies might be willing to finance the job. This was not pursued further at the time because of the fact that the overall budget of the Association was currently undergoing revision and it was considered advisable to postpone individual requests until this matter was settled. It is hardly necessary to say, however, that the question of financing publication of the pamphlet should now be pushed without delay.

Subsequent to the committee meeting, a tentative outline of the text and a dummy copy of the pamphlet were prepared and discussed with a New York printer.

At the last meeting of the Statistics Section in Atlantic City it was suggested that the Committee on Opportunities consider a compilation of information on graduate public health courses available to statisticians. Dr. Margaret Martin is now exploring the need for such information and ways and means of obtaining it.

The committee also discussed the need for acquainting vocational guidance officers with the jobs available to statisticians in public health and related fields. (This project was also reported to the Section at the last meeting.) It was the consensus that the effort should be to acquaint selected guidance officers —probably 10 or 12— with the whole field of public health rather than with public health statistics alone. It was suggested that the period of instruction should be of possibly two weeks' duration with one week devoted to lectures and seminars and another to field observation. As a solution to the problem of recruiting more and better public health personnel, this would be a small beginning indeed. But as an experiment in one of the ways of accomplishing the purpose, the project would be most valuable. Although the discussion clarified to some extent the thinking of the committee members on the subject, the project has not been developed further, chiefly for reasons of financing as stated above. The committee believes that this effort should now be given renewed consideration.

Since it impinges on all other topics with which the Committee on Opportunities is concerned, the question of field training for Statisticians was included in the agenda of the April meeting. The discussion related particularly to field training or orientation for potential statisticians entering the public health field. The discussants took cognizance of the fact that individuals just entering the field of public health statistics come from a variety of backgrounds, and that this is wholly desirable. No one type of field orientation would answer the needs of all these individuals; yet all need some type, and it is hoped that the Association will make specific recommendations with regard to this subject. The committee's discussion in April centered particularly on one type of individual, the young college graduate whose academic training included mathematics and statistics, preferably with one or more of the physical sciences, and who has had no work experience in public health. It was agreed that the immediate problem was to get these people trained on the job as rapidly as possible so they could fill some of the many vacancies in statistical positions with some degree of responsibility. It seemed to the group that a combination of supervised work, on the job, and academic instruction of a highly specialized sort (not necessarily

leading to a graduate degree) was the best expediency. The Tennessee Department of Public Health and the Department of Preventive Medicine of Vanderbilt University Medical School jointly worked out such a program which has already been reported to this Section. As a result of the committee meeting in April, the statistics and research section of the American Cancer Society and New York University have begun such a training program. This program is to be reported soon in the Association's *Journal*.

The Committee on Opportunities in Statistical Work contemplates no particular action on the subject of field training, but since this is a subject closely related to that of recruitment of personnel, it feels that it is important to bring it to the attention of the Section and interested individuals on every possible occasion.

At a business meeting of the Statistics Section in Boston, November 9, 1948, the Committee on Professional Standards and Remuneration and the Committee on Opportunities in Statistical Work were terminated. A new Committee on Opportunities and Functions of Statisticians was appointed, to combine with new functions some of the previous activities of these committees.

ELLEN W. JONES, Commonwealth Fund, New York, N. Y., *Chairman*
PAUL M. DENSEN, D.Sc.
MARGARET P. MARTIN, PH.D.

Standards and Remuneration*

Statistics Section

THE task originally assigned to the Committee on Remuneration and Standards was that of developing, if possible, a salary scale for professional personnel engaged in public health and vital statistics work. The committee was also charged with the general responsibility of attempting to formulate standards for statistical positions in health departments.

Examination of reports made by other Sections of the Association and discussion with the chairman of the Section's Committee on Opportunities in Statistical Work and of the Committee on Professional Education's Subcommittee on Educational Qualifications of Personnel in Vital Statistics and Vital Records led this committee to the realization that the existing lack of definition of the purpose and function of a statistician in a health department made it almost impossible for the committee to carry out its original assignment.

The committee reached the conclusion that a necessary preliminary to the eventual development of salary scales and professional standards was a survey of the existing situation with respect to salaries, background, duties, and qualifications of public health and vital statisticians. It was felt that information should also be sought on the methods by which present personnel had entered the field because of its bearing on the future development of professional standards and because such information would be of value to the other two committees working in the field.

Accordingly, in the summer of 1947 the committee undertook a survey of the following classes of personnel in state health departments:

1. All personnel classified as statisticians
2. All personnel doing analytical work demanding some knowledge of statistical principles and methodology
3. All personnel engaged in vital records registration at a professional or policy level
4. Other personnel considered by the reporting agency as properly belonging to the statistical group

The questionnaire used in the survey asked for the individual's job title, his remuneration, a description of his duties in his own words, his education; and the particular circumstances which led to his entrance into the field of statistics in general and public health statistics in particular. These data were obtained from personnel in 43 state health departments, largely by a series of direct visits by a representative of the Division of Public Health Methods, U. S. Public Health Service, supplemented by mail questionnaires to those departments which could not be visited.

This report presents the results of this survey. A brief discussion of the classification scheme adopted by the committee is essential before discussing the findings. The classification was made with reference to job descriptions only; jobs which the committee considered to be equivalent in responsibility being grouped without reference to salary or title.* It is desired to

COMMITTEE ON PROFESSIONAL STANDARDS AND REMUNERATION.
Organized 1946.

emphasize the fact that the scale of classification is continuous in nature and that the dividing line between any two adjacent classes is obviously somewhat arbitrary. The decision to place an individual in one or the other of these classes was based upon the majority verdict of the members of the committee after independent examination of the returns. The classification arrived at is as follows:

Group I (Chief Statistician)—Workers in this category are chiefs of a statistical unit engaged primarily in analytical work exclusive of registration activity. In coördination with other activities of the health department they are responsible for the development of a statistical program from the planning stages through the final analysis and presentation of results. They exercise considerable independence of action within the broad policies laid down by the health commissioner.

Group II (Registrar)—Chiefs of a statistical unit engaged primarily in the registration of births and deaths. Responsible for formulation of policy in relation to registration matters and at times for analysis of the registration function but not engaged in analysis with regard to health department activities as a whole.

Group III (Chief Statistician and Registrar)—Chiefs of a combined registration and analysis unit. These combine the duties and exercise the responsibilities of the Chiefs in Groups I and II.

Class A (Assistant Registrar)—Individuals in this group usually function under the immediate supervision of someone in Group II. They ordinarily engage in no analysis but are given considerable responsibility for the routine production of vital statistics and may be directly in charge of a large clerical office. When necessary they may act in the place of the person in charge of the registration unit.

Class B (Senior Statistician)—Under the general supervision of individuals in Group I or Group III they are responsible for analysis of a high order of technical competence demanding a good general knowledge of public health. May consult with chiefs and other personnel of the health department with regard to planning of a study, collection of data, tabulation and analysis of results. Under general supervision only, may initiate studies and exercise considerable independence of action within broad policy lines laid down by the chief. Analytical work not confined to one particular aspect of public health.

Class C (Junior Statistician)—Individuals in this class are usually under the immediate and fairly close supervision of individuals in Class B. They do not confer, except on rare occasions, with chiefs of other divisions. They may supervise a small clerical or tabulating force or be responsible for some tabulating work.

FINDINGS

The Number of Statistical Workers in the Different States (Tables 1 and 2)—

Almost half the states for which returns were tabulated had only one statistical worker, although one state had 16. If Groups I, III, III-B, and III-C are put together and for convenience sake called "analytical" workers, there are 17 states with no "analytical" workers at all.

When the states are ranked according to expenditures for public health in 1947, it is found that of the 70 "analytical" workers, 56 are in the states in the two upper quartiles with respect to expenditure. (It should be remembered here that the data are heavily

weighted by the returns from 3 states which have 32 of the 108 statistical workers.)

The committee feels that these facts are of considerable significance when taken in relation to the expanding nature of public health as evidenced by the development of cancer programs, rheumatic fever programs, medical care programs, etc. If it be granted that the function of the statistician in the health department is to aid in the definition of public health problems, to suggest points of attack upon these problems and to evaluate the success of the program, then the lack of any "analytical" workers in many of the states represents a serious deficiency in the development of public health programs.

The data in these tables also carry implications for the training of statistical workers. Many of the states in the lower two quartiles have only a registrar at the present time. It is important, therefore, that the registrar have some kind of training in the analytical phases of public health and vital statistics. Even should the state manage to get funds for a separate "analytical" worker, the registrar should have had some training in this field because he will be called upon to work with this "analytical" person and in some cases to supervise him. Conversely, it is desirable that the training of the "analytical" worker include a grounding in the fundamentals of registration, especially because many of the newer public health programs have a registration feature about them.

The committee would also like to make the point that the states which may be able to afford only one well trained statistical worker in the sense used here, have an inducement to offer in the form of a variety and scope of problems which in itself represents a stimulating opportunity. It would be better in this respect to pay a sufficiently high salary to attract one worker of this type, than to attempt to get workers of mediocre ability at a lower salary.

Salaries—

The facts with respect to salaries are set forth in Tables 2, 4, 5, and 6. Very few individuals command a salary of $6,000 or more per annum and the majority are paid salaries under $4,000. The highest salaries are paid to individuals in the registrar group. Of the 31 individuals performing senior statistician work only 4 command a salary over $4,000 and there were 6 individuals in this class receiving less than $3,000 per annum. Furthermore, this low salary scale is not due to a concentration of individuals in the states falling in the two lowest quartiles with respect to

expenditures for public health. More than half the individuals doing senior statistician's work in the opinion of the committee are in the states in the two upper quartiles. This illustrates the committee's contention that it is difficult to recommend salary scales until there is a clearer definition of function.

Further evidence on this point is yielded by Tables 5 and 6 in which the salaries of directors of statistical units are compared with those of directors of other services in state health departments. It is noted that medical directors, directors of laboratory services, and sanitary engineering directors jockey for first position for both starting and top salaries. These are the three groups whose function in the health department is pretty well defined and for whom professional standards have been stabilized. The three groups for which standards and function are relatively ill-defined fall at the lower part of the salary scale. Effort must be bent to clarify the place of the statistician in the health department. The committee believes that when this is done salaries will tend to rise and standards will be more meaningful.

Method of First Making Contact with the Field—

Of the 108 individuals for whom the information was available, 41 first made contact with statistics in general through the social sciences, 48 through the biological sciences, and 17 through mathematics (Table 7). However, of those who entered statistics through the social sciences most first learned of the subject through courses of one kind or another, whereas only about one-third of those making contact through the biological sciences did so through the media of courses. So far as the mathematical group is concerned, almost all can be considered as having learned about statistics through courses.

The significance of these facts for public health and vital statistics is twofold. People are not hearing about statistics when they come through the biological side of college work. They have to get out and work for a while and come to it more or less by chance in their employment. But public health, of course, has a considerable biological background. The result is that the people with biological science background tend to come into the field lacking any training in statistics while those who received such training through the social sciences tend to be deficient in biological background. A proper balance of the two is to be desired.

The replies to the question concerning the method of *first* learning about public health or vital statistics also bear out the foregoing points (Table 8). A little more than half of the replies indicated that the individuals learned about public health statistics more or less accidentally. Only 21 learned about the

field through a teacher or a college employment office. This would indicate that the undergraduate student—and more particularly, his teachers and advisers—are not made aware of the field.

The result of this state of affairs is that when individuals do enter the field, a good part of their training is behind them, which results usually in gaps in their training from the standpoint of public health.

Educational Background—

The data in Tables 9 and 10, on educational background on those now in the field, substantiate these conclusions. In 1938 the Committee on Professional Education recommended at least one year of graduate professional education leading to a Master's degree or certificate subsequent to graduation from college and at least 3 months of directed practical public health experience in a recognized public health or other agency. Nearly a decade later the committee's findings indicate that nearly three-fifths of the workers in the field had no graduate public health degree and nearly one-third had no more than an undergraduate degree. These data do not accord very well with the recommendations of the Committee on Profes-

sional Education, particularly when one realizes the strides that have been made in the field since those recommendations were made.

A similar picture exists with respect to the mathematics and statistics backgrounds of persons in the field. Of the 108 returns, 23 showed no college mathematics at all, and only 51 of the 108 went through calculus. Even among the analysts only 38 had had a course in calculus. It is desirable that at least an elementary course in calculus be required in order that there be some basis for understanding the nature of the reasoning that results in the development of statistical theory. In so far as formal background in statistics is concerned, 23 had no statistics courses at all and 36 depended upon other fields than public health for their statistics. Although the majority of those without statistics are registrars, the point has previously been made that it is desirable for the registrar to have had such a course.[1]

It is clear that the standards suggested by the Committee on Professional Education are not being met. A quotation from a recent article in *Public Health Reports*[2] is appropriate:

"In 1947 less than 25 per cent of the classes of statistical positions in the state health departments had requirements which even approached those recommended by the Committee in 1938."

CONCLUSIONS

While the present salary scale of statistical workers in state health departments is low, the committee feels that it is essential to develop a clear statement of the duties and responsibilities of each class of statistical position in the health department before salary scales or professional standards which might be suggested can be meaningful.

The committee also feels that one of the necessary steps to improvement of professional standards for statistical workers in public health is to make those who guide the undergraduate student aware of the needs of the field, and of the background desired in personnel wishing to enter the field. It is unrealistic to suppose that the mere setting of standards will overcome some of the gaps in the training of personnel entering the field if those who guide that training are unaware of these standards.

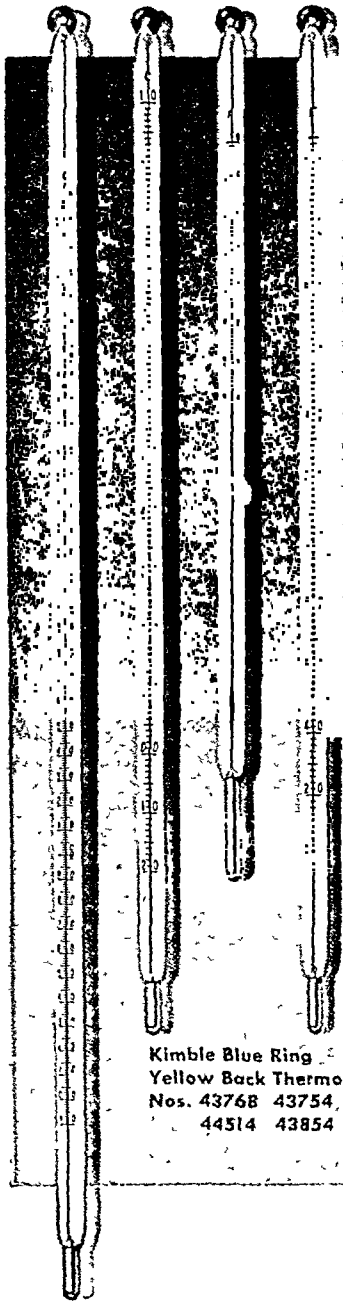
Clinically approved



Today, there is a wealth of clinical evidence supporting the use of Meonine as a supplement to the protein-rich diet usually prescribed for liver damage associated with malnutrition, pregnancy, allergy, certain chemical poisons, and alcoholism.

Typical of this evidence is a Beams-Endicott paper[1]. The authors reported that a methionine supplement seemed to cause regeneration of the liver parenchyma in cirrhotic patients, irrespective of the amount of protein and vitamins in the diet.

Complete bibliography on request. Meonine is supplied in 0.5 gram tablets. Wyeth, Phila., Pa.

Retested . . . Accurate . . . Readable . . .

Kimble Blue Ring Yellow Backs are here!

KIMBLE GLASS . . . foremost maker of precision laboratory glassware . . . proudly presents this outstanding new line of retested, accurate, easily read thermometers. Every item in this new line is *retested* to insure its accuracy.

Precise! There is a Kimble Blue Ring Yellow Back Thermometer for each scientific specification—ASTM and other special-purpose thermometers—National Bureau of Standards thermometer specifications . . . can be N.B.S. Certified if required.

High visibility! The yellow back behind the column and the *new style horizontal* numbering insure speediest and most accurate reading . . . save your time and minimize possibility of error.

Look for the blue ring on top that instantly identifies genuine Kimble Yellow Backs.

If your laboratory supply dealer does not yet have Kimble Blue Ring Yellow Back Thermometers, write us for the names of the nearest dealers who have them.

MEASLES

—without fear of side reactions

There's one sure way of silencing crying youngsters and nervous mamas who complain about reactions – specify Cutter Immune Serum Globulin–Human. Successful results with this product are not happenstance. They come from:

1. The right raw material—fresh venous blood from normal donors.
2. The water-clarity of a hemolysis-free and non-pyrogenic product.
3. The concentration of 160 mgm. per cc. of gamma globulin—maintains consistent globulin potency yet permits low volume adjustable dosage:

For prevention—
0.1 cc. Immune Serum Globulin
For modification—
0.02 cc. Immune Serum Globulin
} *intramuscularly, per pound body weight*

Prepare now for measles' peak season just ahead. Notify your pharmacist the amount of gamma globulin you expect to use—and specify Cutter.

YANKEE ROTATORS

for

V.D.R.L. (Cardiolipin) test for syphilis
Boerner-Jones-Luken, Mazzini, Kline Tests
Blood banking—Other mixing operations

Yankee Rotators simulate hand mixing by imparting a gentle circular motion in the horizontal plane. They are designed for micro slide agglutination tests, blood typing and grouping tests, mixing solutions in flasks, beakers, etc. and many other procedures where gentle continuous mixing is indicated Three types are available, to meet the requirements of different procedures.

A-2271 and A-2276, designed for the V.D.R.L. (Cardiolipin) test for syphilis, rotate at the required rate of 180 RPM.

A-2275 and A-2276, for the Boerner-Jones-Luken, Mazzini, Kline and other micro slide agglutination tests, rotate at 130 RPM.

A-2280, for use in blood banking to mix the anti-coagulant with the donor's blood as it is being received, rotates at 100 RPM.

A-2270 and A-2271 accommodate twelve 3 x 2" concavity slides or a number of large containers. A-2275 and A-2276 accommodate six 3 x 2" concavity slides or one large container. A-2280 accommodates one 600 or 750 ml. plasma bottle All models except A-2280 have a built-in timer which can be set to shut the motor off automatically after a 2 to 5 minute mixing period; the timer can be cut out of the circuit when continuous operation is desired.

A-2270 Yankee Rotator, 11 x 11" platform, 130 RPM, with automatic timer; for 110 v., 60 cycle AC.....Each $52.50

A-2271 Yankee Rotator, 11 x 11" platform, 180 RPM, for the V.D.R.L. (Cardiolipin) test for syphilis; with automatic timer; for 110 v., 60 cycle AC.....Each $52.50

A-2275 Yankee Rotator, 8 x 8" platform, 130 RPM, with automatic timer; for 110 v., 60 cycle AC..... Each $45.00

A-2276 Yankee Rotator, 8 x 8" platform, 180 RPM, for the V.D.R.L. (Cardiolipin) test for syphilis; with automatic timer; for 110 v., 60 cycle AC.....Each $45.00

A-2280 Yankee Donor Blood Rotator, 8 x 8" platform, 100 RPM, without automatic timer; for 110 v., 60 cycle AC.....Each $40.00

DETERGENT and SANITIZING Solutions *Automatically* Mixed for Hand Dishwashing

WHY WORRY?

Let us solve your dishwashing problems. The AUTO-CHLOR SYSTEM assures you the very best detergent and sanitizing solutions properly mixed at all times.

INSTALLATION FREE!

There is no charge for AUTO-CHLOR SYSTEM equipment. It is installed and maintained free of charge. You pay only for the solution you use.

ECONOMICAL, DEPENDABLE

The AUTO-CHLOR SYSTEM is fool-proof. It gives you automatic low cost protection against contagion from insanitary eating utensils. Healthy customers mean more profits!

First & Pioneer automatic system for hand dishwashing and sanitizing

These 'picture words' represent a primitive classification of urines used by early Babylonian and Egyptian physicians

centuries to perfect seconds to perform

When Sumerian and Babylonian physicians, *circa* 4000 B.C., noted the varying colors and constitutions of the "water of the phallus," they were probably not the first uroscopists in history. They were assuredly not the last, for fifty-odd centuries were to elapse before Fehling's first paper on the copper reduction test for urine-sugar appeared in 1848.

But centuries to perfect diagnostic procedures are condensed into seconds to perform the reliable *Clinitest*® method for urine-sugar levels. From start to finish, the test takes less than a minute. This tablet method is simplicity itself . . . readily learned by every diabetic patient. External heating is uniquely eliminated by the *Clinitest* procedure. Routine test interpretation is made easy.

Tailors

Outstanding

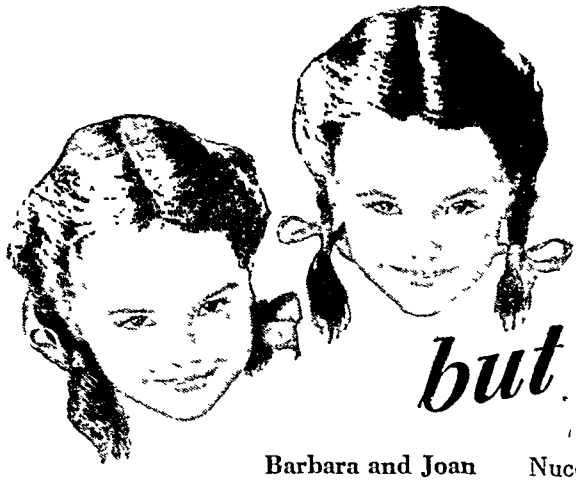
IN TOPICAL ANTIBIOTIC THERAPY

LOW INDEX OF ALLERGENICITY—Bacitracin is outstanding in that its application topically is only rarely complicated by allergic manifestations. It therefore possesses a distinct advantage over many other antibiotics, freeing topical antibiotic therapy from this formerly serious limitation.

WIDE RANGE OF EFFECTIVENESS—While its spectrum of action largely parallels that of penicillin, Bacitracin is destructive to many strains of pathogens which are penicillin-fast. Thus it broadens the scope of antibiotic therapy and enhances its therapeutic efficacy.

PROMPT ACTION—Injected in solution into the base of pyogenic lesions, or applied topically in the form of an ointment, Bacitracin acts promptly upon the bacterial invasion. Response is apparent in most cases within a short period.

INDICATIONS—Bacitracin, topically administered, is indicated in the treatment of many deep pyogenic lesions of the skin, superficial cutaneous pyogenic lesions, and many external ocular infections due to Bacitracin-sensitive organisms. Bacitracin is administered topically only.



Bacitracin, in dry form for making solutions, is supplied in 20 cc. serum-type vials containing 2,000 and 10,000 units, and in 50 cc. vials containing 50,000 units. Also available as Bacitracin Ophthalmic Ointment in ⅛ ounce tubes and as Bacitracin Ointment in ½ ounce tubes, both containing 500 units per Gm. Literature available to physicians on request.

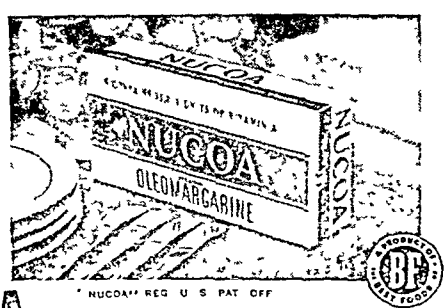
ALIKE~ *but different*

Barbara and Joan —twin daughters of Mrs. Raymond H. Thompson of Penn Wynne, Pa.—look much alike, as you can see by their picture above. But you have only to be with them a few minutes to discover in how many ways they differ.

Brands of margarine differ, too—even when they look alike. For although the principles of modern margarine making are available to all, experience and skill in applying them vary. *Good* margarine is not easy to make.



Why Millions Choose Nucoa Margarine

Best Foods, makers of Nucoa, are not newcomers in margarine making. They have been *leaders* for more than thirty years—and pioneers in the research which has made modern margarine so different from old-time kinds. That is why Nucoa margarine is so dependably nutritious . . . so unvaryingly satisfying in flavor . . . so evenly smooth-churned and luscious in spreading texture. That is why Nucoa is America's most popular margarine.

What Barbara's and Joan's mother says is typical. Like millions of other families during the years of shortage, they necessarily sampled many kinds. "But," says Mrs. Thompson, "as soon as conditions permitted us to *have* a choice, Nucoa became our favorite brand. We like it best for texture and for its *always-the-same* delicious flavor, fresh and sweet every pound."

Base Your Advice on Experience

You, to whom others turn for advice about foods, know that margarine is important in today's nutritious-at-moderate-cost diets. Base your advice on experience and be sure to try Nucoa margarine. When you use Nucoa on your own table, you will discover, we believe, how good, day in and day out, *good margarine* can be.

" NUCOA" REG U S PAT OFF

NUCOA *America's most popular margarine*

MADE BY THE MAKERS OF BEST FOODS AND HELLMANN'S REAL MAYONNAISE

The rewards of this dietary adjustment are *Immediate*

To THE person who habitually skimps on breakfast, or skips this meal entirely, a well balanced, adequate morning meal can quickly prove beneficial. A breakfast providing one-fourth to one-third of the daily nutrient and caloric needs improves morning physical stamina and mental acuity. It also enhances the opportunity of the other two meals of the day to complete the satisfaction of nutritional requirements.

It is estimated that literally millions of children and adults will benefit from this simple dietary adjustment.

A good base on which to plan the morning meal is a widely acclaimed basic breakfast pattern consisting of fruit or fruit juice, breakfast cereal, milk, bread and butter. An important main dish of this breakfast is the cereal serving, consisting of cereal, milk, and sugar.

The tables show the well balanced nutrient contributions of the cereal* serving and the basic breakfast pattern. Economy, tastefulness, and variety characterize both of them.

BASIC BREAKFAST	TOTALS supplied by Basic Breakfast	AMOUNTS supplied by cereal serving
Orange juice, 4 fl. oz.;	CALORIES..... 611	202
Ready-to-eat or Hot Cereal, 1 oz.;	PROTEIN..... 20.7 Gm.	7.1 Gm.
Whole Milk, 4 fl. oz.;	CALCIUM.....0.465 Gm.	0.156 Gm.
Sugar, 1 teaspoon;	PHOSPHORUS.... 488 mg.	206 mg.
Toast (enriched, white), 2 slices;	IRON..... 3 mg.	1.6 mg.
Butter, 5 Gm. (about 1 teaspoon);	VITAMIN A..... 1074 I. U.	193 I. U.
Whole Milk, 8 fl. oz.	THIAMINE..... 0.52 mg.	0.17 mg.

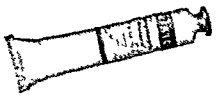
A RESEARCH AND EDUCATIONAL ENDEAVOR DEVOTED TO THE BETTERMENT OF NATIONAL NUTRITION

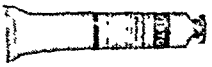


135 South La Salle Street • Chicago 3

Streptomycin *is now available in* Ointment *form*

Here is another original contribution to the antibiotic armamentarium from Bristol Laboratories: streptomycin sulfate for topical application, in a smooth, greaseless, ointment base. This significant development of Bristol research is noteworthy for the following:

1. A Broad Antibacterial Spectrum

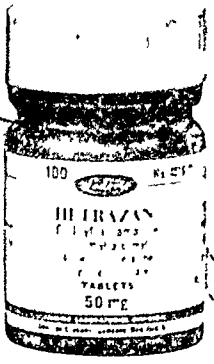


The variety of bacteria destroyed or inhibited by streptomycin is remarkably broad Its antibacterial spectrum surpasses those of other antibiotics in current use for topical application

2. Less Sensitizing

Streptomycin in ointment form minimizes the greatest single objection to topical antibiotic therapy in that it is demonstrably less sensitizing.

3. A Water-Soluble Ointment Base



Bristol Streptomycin Ointment is unusually pleasant to use, because it is incorporated in a smooth, water-soluble base Despite the fact that there is no grease or oil, adequate potency can be expected to persist throughout the full dating period of nine months after manufacture

Bristol STREPTOMYCIN OINTMENT is indicated in skin and wound infections due to streptomycin-sensitive organisms. Each gram of the ointment contains 5000 micrograms of pure streptomycin.

Available NOW from your usual source of supply, in 1 oz. tubes, singly, or packed 12 to a carton.

HETRAZAN*

DIETHYLCARBAMAZINE

LEDERLE

Stability in the Tropics

This new organic compound may be given easily by mouth, is almost immediately effective against the microfilariae in the blood stream and tissues, and is stable at the high temperatures that prevail in the tropics. It tends to end infestation with bancroftial filariae in 3 to 4 weeks and may be used to stamp out the infestation in whole populations.

Clinical tests made in India, Africa, the South Pacific, the West Indies, and Central America have established its clinical use.

PACKAGES: *Bottles of 100 and 1000 tablets*

*Reg. U. S. Pat. Off.

High power photomicrograph (X 210) of microfilaria of W. bancrofti *in human blood. The red blood cells have been dissolved, leaving only the microfilaria and the white blood cells.*

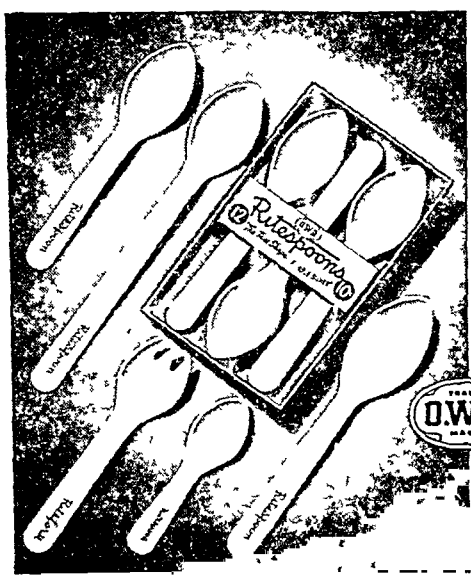
Cold



So what?

Cold weather increases the difficulty of maintaining sanitation in public refreshment places. But the assured cleanness of single service spoons and forks can be maintained by use of OWD Ritespoons and OWD Ritefork.

Complete utility of OWD Ritespoons in hot beverages, and semi-liquid hot foods gives these smooth, beautiful disposable utensils a wide range of application in winter as well as summer.

Nationally Advertised
All Year 'Round
To Every Consuming Class

● Made of naturally pure hard wood in the true shape and with the full bowl capacity of metal ware. Strong, rigid, smooth, tasteless, odorless. 4 sizes and OWD Ritefork meeting every food and beverage service need. In bulk cartons, individually wrapped, and in 10-cent cellophane over-wrapped trays. Write for samples.

O.W.D. Ritespoons®

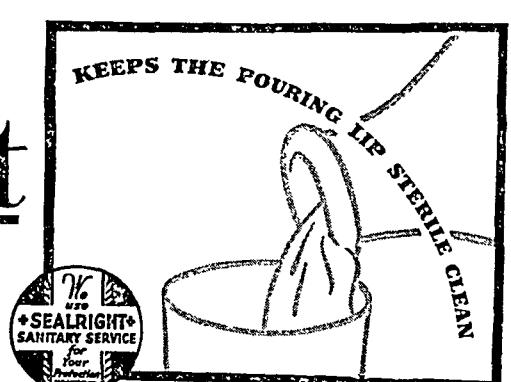
(with apologies to Tennyson)

If there is one place on a milk bottle which should never be promiscuously handled—that place is the pouring surface.

The reason is obvious.

Every drop of milk in the bottle must pass over that pouring surface before it can be used.

No wonder health authorities and public spirited dairies are so insistent upon *sealed* protection of that pouring surface from dairy to home.



In every state and in many foreign countries, Sealright Sealon Hoods are keeping milk bottles safe against contact with hands, melting ice, rain, snow or dusty air. *They protect all the way to the home.*

New Hammertone Finish

The International Clinical Model is now finished outside in durable glistening light gray hammertone and inside in glossy baked white enamel. Both finishes are products of modern paint chemistry — both are baked on at high temperature — both are hard and smooth, do not chip, are easy to clean and resistant to chemicals. Mechanically the Centrifuge is the same reliable product you have known for years.

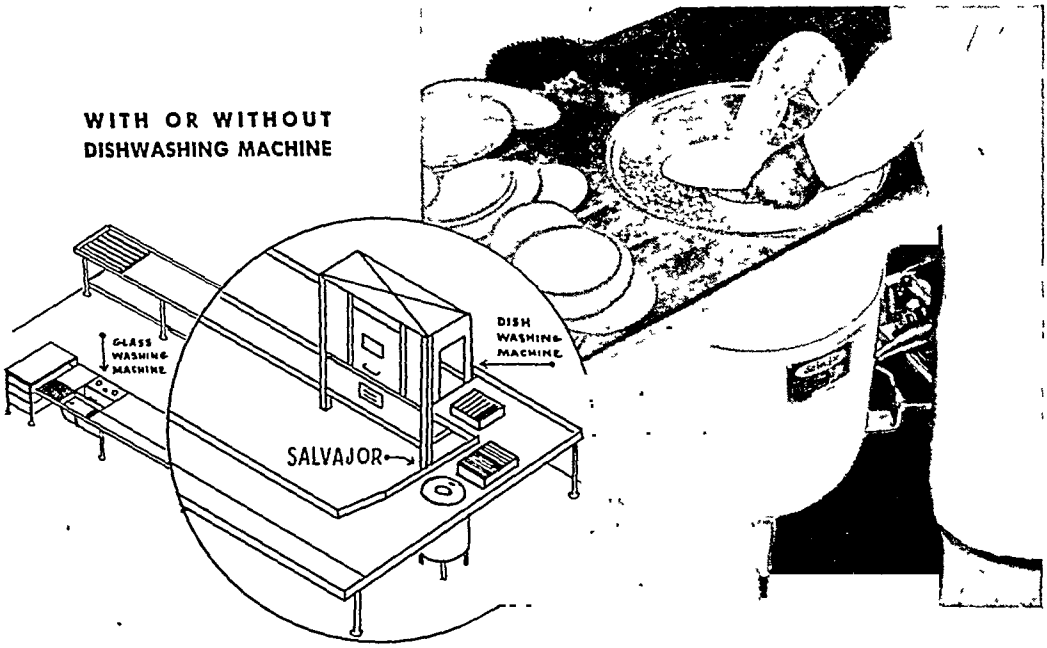
POSITIVE PROTECTION

COMPLETE CONVENIENCE

● These TWO Dacro P-38 Caps make it possible for dairies to give every customer the protection of Dacro Sealed milk . . . with the added "convenience feature" of a cap that can be removed by hand for the store and school trade. Both caps completely safeguard the purity of bottled milk and provide operating advantages and economies that are welcomed by dairy plant operators.

STEEL . . . *for the Home Delivery Trade*

An air-tight seal as well as a cover cap. Because it is made of steel, this cap is exceptionally strong and durable. It is also tamper-proof. Easily removed in the home with the special Dacro Opener. Makes a perfect re-seal, which may be snapped back on the bottle as often as needed.



ALUMINUM . . . *for Store and School Trade*

An air-tight seal as well as a cover cap. Because aluminum is somewhat softer than steel, this cap may be removed by hand, thus eliminating the need for an opener in distribution to stores and schools. Makes a fine re-seal, which may be snapped back on bottle as often as needed.

Dishwashing SANITATION Insurance

AMERICA'S Leading SANITATION EXPERTS Recommend SALVAJOR* the Modern SCRAPPING & PRE-WASH MACHINE . . . .

for any Size DISHWASHING DEPARTMENT

For large or small dishwashing space Salvajor performs the essential pre-wash as it scraps with one constant stream of tepid water.

Salvajor initiates the attack on bacteria at its source. Dangers that lurk in garbage waiting for disposal are neutralized by Salvajor's sanitary garbage disposal basket. Bacteria-laden food particles are kept from the dishwashing machine by the thorough pre-wash.

Designed to comply with every rigid test prescribed by sanitarians, Salvajor is made of easy-to-clean, non-corrosive metal. Even hard-to-reach germ breeding corners and crevices are eliminated in the design.

Salvajor Sanitation Insurance is available to food serving institutions of every size. Public Health officials are invited to write for full details.

*Trademark Reg. U S. Pat Off

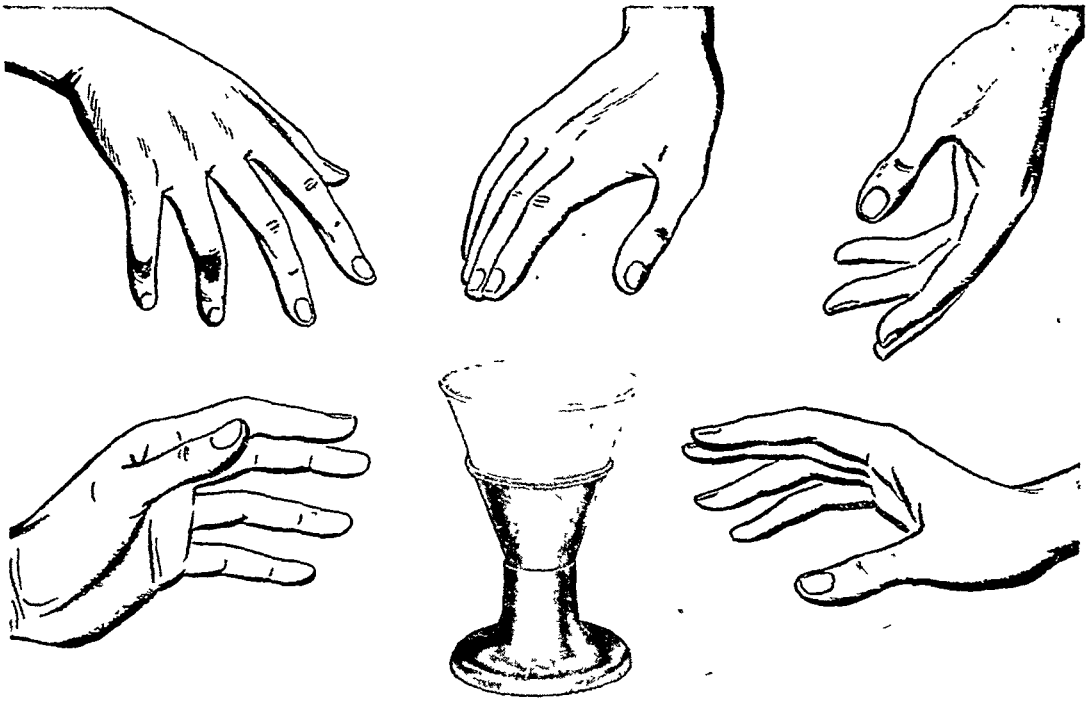
PROVE CAMEL MILDNESS for Yourself!

R. J. Reynolds Tob. Co., Winston-Salem, N. C.

According to a Nationwide survey:

MORE DOCTORS SMOKE CAMELS THAN ANY OTHER CIGARETTE

Doctors smoke for pleasure, too! And when three leading independent research organizations asked 113,597 doctors what cigarette they smoked, the brand named most was Camel!



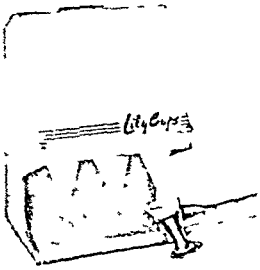
Test for yourself what throat specialists reported when a 30-day smoking test revealed:

"NO THROAT IRRITATION due to smoking CAMELS!"

MAKE YOUR OWN 30-DAY CAMEL MILDNESS TEST. Smoke Camels, and only Camels, for 30 days. Prove for yourself how mild Camels *are!*

Hundreds of men and women, from coast to coast, recently made a similar test. They smoked an average of one to two packs of Camels a day for 30 days. Their throats were carefully examined by throat specialists. And after a total of 2470 examinations—these throat specialists reported *"not one single case of throat irritation due to smoking Camels!"*

But prove it yourself...in your "T-Zone" (T for Taste and T for Throat).

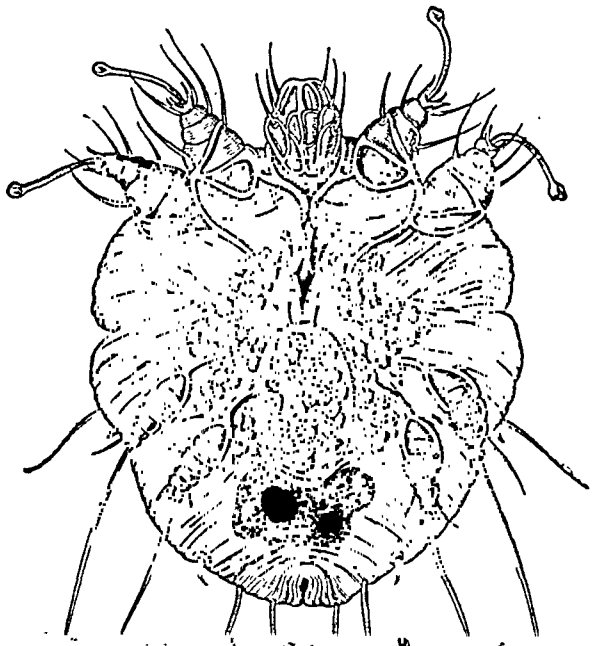


Hands Off!

With the Lily* "Magic Grip" Cup Holder no such sign is needed for fountain clerks! *Hands need never touch the cup.* Clerks just slip the holder over the cup. The "Magic Grip" picks up a single cup—holds it firmly while drink is prepared, served, consumed. —And only ONE size holder is needed for every size cup—from 5 to 16 oz.

Toppling cup stacks? Exposure to dust?—Not with the Lily 3-in-1 Cup Cabinet! This dustproof, satin steel cup housing holds any 3 sizes of Lily Vee Cups*... 700 in all. It's an ideal teammate for the "Magic Grip"... speeds service...eliminates cup losses...saves space.

Recommended for all establishments serving food and drink, this winning team for faster, more efficient fountain service offers economy, speed—*and* more satisfactory sanitation! LILY-TULIP CUP CORPORATION · New York · Chicago · Kansas City · Los Angeles.



*T M REG U S PAT OFF

Lily Cups

WORLD'S LARGEST MANUFACTURER PAPER CUPS & NESTED CONTAINERS

A NEW *effective* treatment for Scabies

No longer are slow, greasy ointments with their attendant messiness necessary to treat scabies. In their stead has come quick, easily applied, highly parasiticidal benzyl benzoate emulsion. • • • Writes Mackenzie[1]: "The ease and speed with which the application can be carried out...rapidity of cure, and the almost immediate relief from itching combine to make it a satisfactory remedy from both the clinical and the public health aspects."

'WELLCOME' **BENZYL BENZOATE** EMULSION 50%

Application: Following a thorough soap and water bath, the emulsion (diluted to 25%) is painted on the entire body, allowed to dry, and then reapplied. A warm bath, 24 hours later, completes the treatment.
Bottles of 4 fl. oz. and ½ gal.

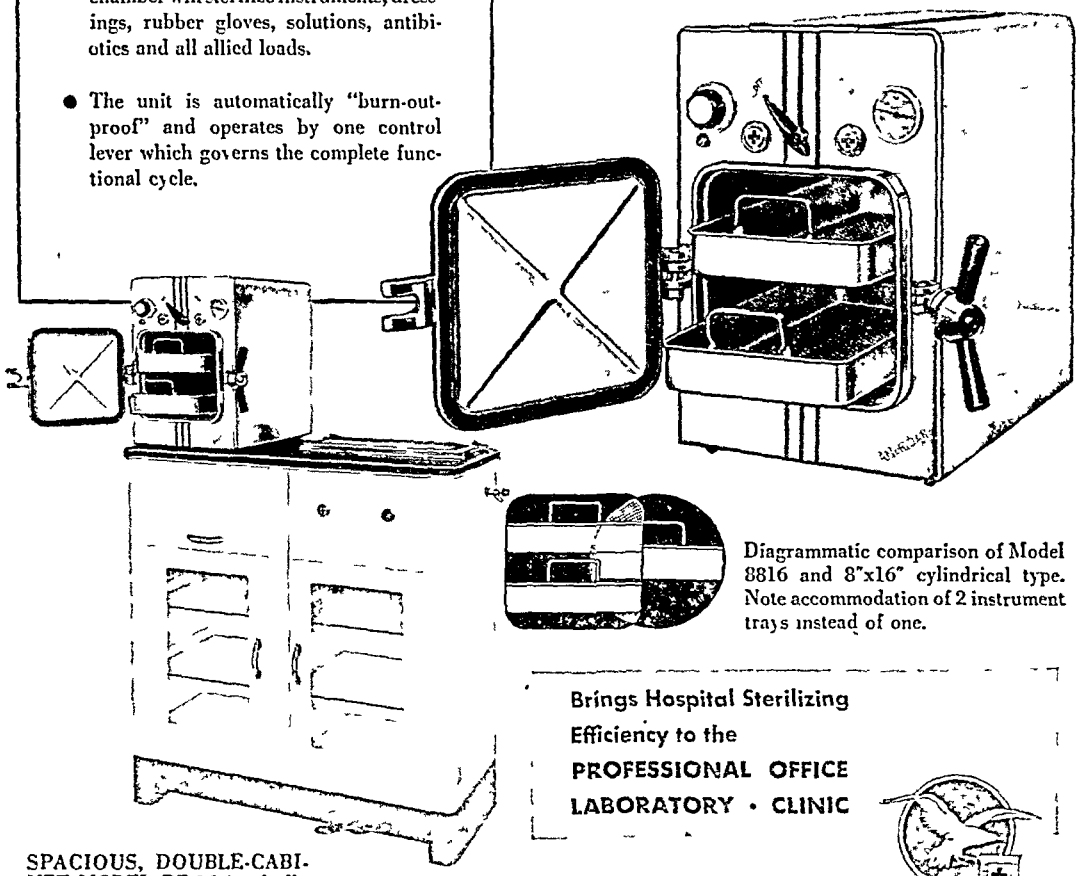
Increases Load Capacity by 100%

... accommodates 2 instrument trays instead of one



The "American"

All-Purpose JUNIOR AUTOCLAVE

(MODEL 8816)

- Fully automatic and self-compensating for all types of loads.
- Requires no valuable floor space. May be placed on any flat surface and operated from convenient electrical outlet.
- This all purpose unit with 8"x8"x16" chamber will sterilize instruments, dressings, rubber gloves, solutions, antibiotics and all allied loads.
- The unit is automatically "burn-out-proof" and operates by one control lever which governs the complete functional cycle.

Presents a radical departure in autoclave design that meets every requirement wherever a single, pressure steam sterilizer of small size is indicated. Duplicates in every respect the efficient, precision performance of standard size "American" Surgical Supply Sterilizers widely used in hospitals.

Diagrammatic comparison of Model 8816 and 8"x16" cylindrical type. Note accommodation of 2 instrument trays instead of one.

Brings Hospital Sterilizing Efficiency to the PROFESSIONAL OFFICE LABORATORY • CLINIC

SPACIOUS, DOUBLE-CABINET MODEL DB-16 is ideally constructed to accommodate MODEL 8816, thus combining the essentials of a practical Surgical Supply for the private office.

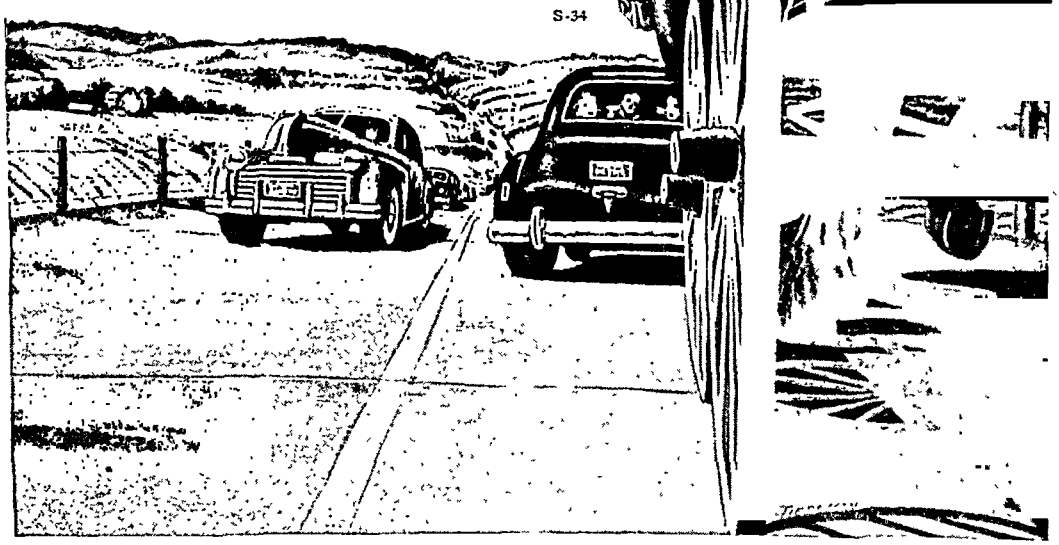
HORSE and BUGGY METHODS ARE OUT IN SEWAGE TREATMENT TOO!

Sewage treatment without chlorination is like using a horse and buggy instead of a car. It can be done but it requires more time and takes a lot more effort to get the same results.

Chlorination in sewage treatment has proved its worth, through actual use in reducing such troubles as SLUDGE BULKING, FILTER PONDING, SULFIDE CORROSION, and ODORS. Moreover chlorination by W&T means that your installation will be scientifically engineered and carefully tailored to meet your particular needs.

To call on W&T's 35 years' experience in chlorination and start your plant on the road to modern sewage treatment, just get in touch with your nearest W&T Representative, or write Newark 1, New Jersey.



NEW . . . *The Program Controlled Chlorinator with Centrifugal or Aspirator Injector. Manual or program operation to meet all sewage flow demands.*

High Points of the Boston Meeting

An Informal Symposium*

CHAIRMAN, DR. R. M. ATWATER: I wish you to know that this is not a rehearsed program, but one which brings you, in a conversational tone of voice as it were, the experience of those who attended each of the sessions and who have been in a position to watch for highlights as they came along. Each of these persons has been asked to present what in his opinion are the highlights of the Section or special interest with which he is identified, and we are going to begin with a representative of the Food and Nutrition Section. The speaker is Dr. Stare, Professor of Nutrition at the Harvard School of Public Health here in Boston.

DR. F. J. STARE: In my opinion, the *pièce de résistance* in the meetings of the Food and Nutrition Section was a symposium yesterday morning on Nutrition and Resistance to Disease, and I think the highlight of that Section was the paper by Dr. Howard Schneider of the Rockefeller Institute.

The nutritional state of the host plays a significant rôle in determining resistance or susceptibility to infection, but it is difficult to demonstrate such effects experimentally or to attribute unequivocally the effects observed to specific nutrients. For the last several years, Dr. Schneider has been doing excellent work on the problem, using mouse typhoid as a test problem. Well aware of the many environmental patterns and characteristics which might tend to condition the results of his experiments, he has painstakingly used extremely rigid controls. He has demonstrated that mice receiving a "natural diet" were more resistant to mouse typhoid than those receiving a so-called "synthetic diet," in which all nutrients were well defined. Survival rates ran as high as 25 per cent higher in the animals receiving a natural diet.

Increased resistance to infection in Dr. Schneider's mice was reproducible in groups of mice receiving the diets containing whole wheat only if the mice were derived from strains which were genetically heterozygous, in other words, mixed strains. Such resistance could not be demonstrated in mice which, by strict in-breeding, had been made more nearly homozygous.

Continuing his studies further, Dr. Schneider has shown that the character of the bacterial population is also im-

* A slightly condensed transcription of informal oral presentation at a symposium held at the meeting of the American Public Health Association in Boston on November 12, 1948.
The speakers have not had the opportunity of correcting their statements in final form.

portant in regard to the effect of a component of the diet on resistance to infection. It can be demonstrated better if a mixed strain of the organism, not a pure strain, is used.

Thus, in this particular host-pathogen relationship, it has been shown that to demonstrate an effect of diet, it was necessary to have: (1) a host population that was genetically heterozygous, and (2) a bacterial culture of varied composition. These conditions, essential for the dietary effect observed here, are precisely those which prevail in practice in the world at large, namely, mixed infections and mixed populations.

The nature of the substance in whole wheat which is effective in increasing survival rates of mice to mouse typhoid has not yet been ascertained.

CHAIRMAN ATWATER: Thank you, Dr. Stare. Before you go away from the microphone, let me ask whether there were other papers on the program that struck you, as a representative of Food and Nutrition, as having particular interest, I mean, those that conceivably concerned personnel and personnel practices and recruitment and finance and all those basic things that are common to us all.

DR. STARE: Yes, another section that was particularly interesting was a section devoted to the techniques and the problems involved in teaching nutrition to medical officers and other types of public health officials.

CHAIRMAN ATWATER: For the second participant, we are going to ask the chairman of the Standing Committee on Research and Standards, Dr. Thomas Francis, Jr., to report on the highlights of the work of the Standing Committee. Dr. Francis, in his regular capacity, is Professor of Epidemiology at the University of Michigan School of Public Health in Ann Arbor. His Standing Committee covers not only the standards on milk and water and sewage and bathing places, shellfish, and other standards of the Association, but a whole area of research which includes the New Coördinating Committee on Laboratory Methods.

DR. THOMAS FRANCIS: Dr. Atwater, I would like to say, before reporting on the activities of the Research and Standards Committee and its highlights, that perhaps the highest light of the entire meeting was, to me, the group which is here this afternoon. There is an old saying that the mind can only absorb what the seat can endure, and I think that the fact that the thirst for knowledge is as great as it is this afternoon is a real tribute to our Association.

The other outstanding thing is the high caliber and critical nature and scientific level of the papers which have been presented on most of the programs that I have had the privilege to attend.

I think it has been a very unusual opportunity even for those who are actively interested in biological research. It has been my privilege, and I appreciated it more the last few days than ever before, to serve as chairman of a committee made up of members who have astounded me with their energy and initiative and the enthusiasm with which they do things.

Under the Committee on Research and Standards, we have one large committee, the Coördinating Committee on Laboratory Methods, which was previously a sectional committee that for many years functioned very effectively under the Laboratory Section. But because of the increasing scope of its work and because of the increasing need for a coördinating committee on other levels, it was made a part of the Committee on Research and Standards.

The activities of this committee have been of outstanding significance during this past year. They have resulted in the publication of a new edition of *Standard Methods for the Examination of Dairy Products,* which has already had a wide sale; of the first book of its

kind, *Diagnostic Procedures in Virus and Rickettsial Diseases*. The committee has displayed increased activity relating to the sanitary examination of food utensils. It has dealt with the continued work of Dr. Winslow and his committee and his associates in the hygiene of housing, a field which has been remarkably progressive and to which they have made handsome contributions.

The third subcommittee that I would like to mention is that on the control of communicable diseases. As you will realize, the pamphlet or small booklet which has been published, now getting ready for its 7th edition, under the auspices of the Committee on Research and Standards and under the active direction of Dr. Haven Emerson, has become really a standard book throughout the world. The last edition, that of 1945, was translated into at least six foreign languages. It has become so accepted as an authority in the review of the problems of communicable diseases that the World Health Organization is actively interested in it. A meeting which has been held during the last week was devoted to revising the report, bringing it up to date with the help of several overseas advisers.

I think it is a splendid thing that something which has grown up within this Association should continue to grow and prove to be such a remarkable contribution not only to the administrative aspects but to the basic scientific aspects of the control of communicable disease.

There are numerous other activities which have continued under this committee but there are a few new ones that are just burgeoning, such as the group representing members of several different associations on the Subcommittee on Air Sanitation. Dr. Alexander D. Langmuir has been asked to serve as chairman of this committee, and they held an organizational committee meeting this week.

I would like also to mention the activities of some of the referees appointed when problems are referred to the Research and Standards Committee as a critical and impartial body. As an example of this type of thing I should like to mention the report of the Referee, Dr. Burgdorf, upon problems involved in isolation hospitals—a very instructive preliminary report which we have asked to have published immediately in the *American Journal of Public Health* because of its application to new developments in medical care and hospital building and management. Then we have referred the problem of dental caries which was discussed a year ago, to a committee who again asked a referee to review the data, and to make a continuing review and survey of that problem.

CHAIRMAN ATWATER: I never hear the recounting of those new activities without a thrill.

I am grateful to Dr. Francis for having summarized so briefly. He has spent many heavy hours with these committees and subcommittees and coördinating groups, and we members of the Association ought to be appreciative of this service that is so generously rendered by persons like Dr. Francis and other committee chairmen and committee members.

We will turn now to a representative from the School Health Section, and I am asking Dr. Dorothy Nyswander, Professor of Health Education at the University of California School of Public Health in Berkeley, Calif., interested in the school health problem, editor of one of the best books on that subject, *Solving School Health Problems*, to tell us what the highlights were in that section.

DR. NYSWANDER: Mr. and Mrs. A.P.H.A., your roving woman reporter has attended every session of the School Health Section, which is one of the younger children of your family. She reports as follows:

Prognosis: every indication of better than average development. You, Mr. and Mrs. A.P.H.A., can look forward to having an offspring which will contribute increasingly to maintain your high standard of professional living and be a strength in your old age.

Plans were formulated by the Section Council to bring as many as possible of the 334 members into active participation on two research projects, using consultant advice from other Sections of the Association. The membership of the Section reflects a broad interest in the health of school children. Voluntary agencies, state departments of health, state departments of education, local health departments, local school boards, colleges and universities are well represented in our membership.

Mr. and Mrs. A.P.H.A., did you see the special exhibit of school health materials developed by the Section as part of the National Publicity Council's offering? If not, you have missed something.

Prediction No. 1: I predict that the School Health Section has set a pattern which will be followed by other Sections in bringing together for display and study during the annual convention the newest and best of materials developed on federal, state, and local levels in their respective fields.

We held round tables on three problems—(1) the Nature of School Health Councils; (2) inservice training counsel in health education for teachers; (3) techniques of counseling children with health problems—and kept eager-beaver participants busy for an entire day. Your reporter noted that participants from at least five other Sections came early and stayed late at these round tables. Your reporter saw skillful use of various discussion techniques, including rôle playing, to get concrete situations for analysis by the groups.

What is the difference between giving health advice to parents and children and acting as a health counselor to them? The group was motivated to spell out this difference after hearing this story:

A teacher had asked for short essays about Socrates. One boy handed in these three cryptic sentences.

"Socrates was a Greek.

"Socrates went around giving advice to people.

"Socrates was given poison by the people."

School Health Councils are not established by decree of either school or health department administrators. They are outgrowths of the needs of real people coming to recognize that real health problems demand that many people, including students, analyze the problems and take action together in solving them.

The lecture method of inservice health education for teachers is probably the least effective of the many ways of helping teachers understand the children's needs. The workshop and the clinical case-study methods rank high.

Prediction No. 2: I predict that the round table discussion method for national convention programs will be adopted by other Sections, and I predict further that, unless other sections invest in exploring new methods of group work in their Sections, these Sections will find some of their members transferring to the School Health Section.

Research is fundamental to sound administrative practice in any field. New research related to the health problems of the school-age child at this meeting must be given serious consideration by those responsible for school health programs.

Therefore, *Prediction No. 3:* I predict, Mr. and Mrs. A.P.H.A., that within the next few years, we will see new policies regarding absenteeism from school because of illness and more intelligent use of the information about the causes of such illnesses by teachers and nurses in their work with children.

I predict further that when the evaluation of various audiometric testing procedures for school children is completed, we will see drastic revision of hearing testing programs throughout this country, based on the research presented at one of the Section meetings.

Mr. and Mrs. A.P.H.A., the physically handicapped child has taken a beating for many years. His well-wishers have oftentimes done him as much harm as the people who forgot that he existed. I call to your attention the booklet *Children with Special Health Problems,* which was highlighted in one of our joint sessions. You can obtain it from your local Tuberculosis and Health Association. The School Health Section is proud to have participated in a program in which medicine and education have agreed upon the fundamental principles relating to the care of the physically handicapped child.

Prediction No. 4: I predict that many outmoded ideas and practices pertaining to the physically handicapped child in our schools will disappear wherever active members of the family of Mr. and Mrs. A.P.H.A. take to heart the fundamental concepts presented at this national meeting and embodied in the bulletin *Children with Special Health Problems.*

My informants tell me that the school health program can only be successful when its various parts and its total structure evolve from the thinking and action of many agencies. Kansas reported a study of coöperative effort along these lines which should be read by every member of your family who works in a rural area. Minneapolis reported an exciting venture in two demonstration schools of putting theory into practice. The president of the National Conference for Coöperation in Health Education laid on the line the purposes and accomplishments of this Conference during the past ten years. The Joint Committee of the National Education Association and the American Medical Association reviewed scientifically the principles jointly arrived at in making health appraisals of school children. The guide lines as to the fields in which coöperative endeavors are possible and valuable are ours to follow.

Fifth and final Prediction: I predict that the future will see no substantial forward-looking program of health services or health instruction developed in any city or county of this country which is not an outcome of the coöperative effort of workers in education and health departments, together with their colleagues in the voluntary health agencies and the professional associations.

Signing off until October, 1949, New York City, when we will again give you the latest developments in school health programs.

CHAIRMAN ATWATER: We are moving now to the spokesman for the Industrial Hygiene Section, and I am asking Mr. J. J. Bloomfield of the U. S. Public Health Service, Division of Industrial Hygiene, to report on the highlights there.

Mr. Bloomfield has served on two occasions as secretary of the Industrial Hygiene Section and has also been chairman of that Section. He is a competent observer.

J. J. BLOOMFIELD: The first meeting of the American Public Health Association which it was my privilege to attend was right here in Boston in 1923. twenty-five years ago.

It seems to me that industrial hygiene in my own quarter of a century experience has gone a long way. In the early days, the field of industrial hygiene was a very limited one. We were concerned with finding out the basic fundamentals, investigating and evaluating the strictly occupational diseases. We were then concerned primarily in learning about the etiology of some of these diseases, such as silicosis, about which we knew very little at that time.

Today, we are concerning ourselves with such things as carcinogenic agents in the industrial environment and maximum allowable concentrations of hazardout substances. A host of chemicals have come into play during the past twenty or twenty-five years, for example, ionizing radiation, which is such an important issue, the discovery of new diseases, such as Shavers' disease, and many other new problems that have come in the wake of industrial progress and technological advance.

CHAIRMAN ATWATER: Would you mind telling us what the disease is that you mentioned just now?

MR. BLOOMFIELD: Shavers' disease is not a disease caused by shaving. It is named after Dr. Shaver, who first reported it in Kansas, and is caused by exposure to very fine dust created in the process of converting bauxite in the aluminum industry. It seems that this very fine dust, when inhaled over a certain period of years, causes silicon damage to the lungs. The greatly widened breadth and scope of our field is not only reflected in the quantitative and qualitative character of our work but also in the increasing recognition which it is receiving. A few years ago, only a few organizations—the U. S. Public Health Service, the U. S. Bureau of Mines, the newly created Department of Industrial Hygiene at the Harvard School of Public Health, and a sprinkling of states—were concerning themselves with industrial hygiene problems. Today we have industrial hygiene divisions in practically every state of the Union, in large cities and counties, in large industries with their own research and control departments, in insurance companies, and in a host of other organizations.

Industrial hygiene has indeed grown with the times. It has attained a "new look" along with our fashions. Originally we were concerned with the health of the worker exposed to mercury and lead and silica and so on, and to an increasing array of various chemicals and processes. Today we are even concerned with agriculture. We heard an excellent paper by Dr. Axelrod on the work he conducted among the farmers. Perhaps you think it is strange that industrial hygienists should be concerning themselves with the agricultural population, but farming in this country has become a large industry. We have more than 8,000,000 people in that industry. The farmer is using many machines, insecticides that are poisonous and many other substances that are injurious to health. The migratory farmer is especially subject to disease because of his transitory life and his lack of sanitation facilities; plans are now under way to solve some of the problems among those workers.

On the overall scene, there is a keener appreciation of the importance of the worker's health. The preservation and maintenance of industrial health has various implications. To management it means greater profits and new outlets. To the worker it means employment and a higher standard of living. To the consumer, to you ladies and gentlemen, of course, it means new gadgets and luxuries, television, and other modern inventions. But to the industrial hygienist, technological developments mean headaches because of the potential hazards inherent in new substances and processes, as, for example, radiation energy, new solvents and plastics.

World War II gave impetus to the adoption of a new concept of the "total man." Previously, we had attempted to disassociate the man in his working environment from his home and community environment. The health of the worker during his eight hours on the job seemed to be the sole concern of the industrialist. If he picked up a pneumonia germ somewhere outside of the factory, well, that was too bad for the worker. Industry was not concerned. The war production race, however, with its stress on man power conservation,

revealed that the worker's illness, regardless of its origin, was always costly to management. Sickness absenteeism was expensive in terms of unfilled orders, necessary substitutions and other considerations. Yielding to the pressure of circumstance, the field of industrial hygiene broadened and is continuously expanding to meet the needs of the times. That is why, yesterday, at our joint session with the Medical Care Section, you heard some papers on medical care and the rôle of the industrial hygienist in medical care. This is the result of labor's vociferous cry for adequate medical care for themselves and their families and of management's increasing recognition of the values and economic practicality of such services.

There are still other problems which we must objectively look at and scrutinize and take stock of.

Those of you who were at the joint session of the health officers heard the facts in Dr. Selby's excellent paper in which he pointed out that within his own organization, he had data on more than 300,000 workers, that the most important problems were in the field of rheumatism, arthritis, heart ailments, cancer, and diabetes. These are the chief killers today, and I say to you that industrial hygiene offers a rare opportunity to make an attack on these diseases.

The work of the industrial hygienist is necessarily a team work operation, cutting across all lines. Although he plays a distinct and specialized rôle in the field, he may still serve his colleagues by acting as a spearhead to bring their services to industry's doors. I hope that you will let the industrial hygienist help you to do your job and that you will lend him your assistance with his, so that we can all exert the effort we need toward the preservation and maintenance of public health.

CHAIRMAN ATWATER: Our next spokesman is Dr. Leroy E. Burney, State Health Officer of Indiana and Chairman of the Subcommittee on Personnel Administration.

DR. L. E. BURNEY: The very fine report that Dr. Nyswander gave and the interesting manner in which it was presented merely confirms the conclusion that we have a great deal to learn from health educators.

Recruitment of personnel is the most acute problem facing the public health professions. It is not enough, however, just to recruit personnel. We must utilize all methods available to select qualified personnel. The Merit System Service of the American Public Health Association was established in 1941 to aid in this problem. Its activities have been directed toward developing written examinations for the various categories of professional public health workers.

This has been done with the aid of consultants in medicine, nursing, engineering, veterinary medicine, and other public health groups. Psychologists, psychometricians, and statisticians working closely with subject-matter specialists, construct the test items, develop examinations and their capacity to determine the skills and potentialities of the examinee. The development of these examinations is a dynamic one; a continual effort is made to exclude poor items and establish new and better ones.

It is especially significant that this program has been developed by the organization representing the professional public health workers of our country. It is not dictated by any governmental group. Its consultants and reviewers are recognized practical experts in the various fields of public health and work under the guidance and advice of a voluntary committee of members of the American Public Health Association and outstanding leaders in the personnel field.

Interest in this Merit System Service is most encouraging. At the special session on Thursday morning, the largest crowd ever to attend a discussion on

this subject was present. Most of the group of approximately 300 remained for the duration of the three hour meeting. The life story of an examination for public health workers was the theme. The testimonial of three examinees: health officer, nurse, and engineer was especially interesting, and Dr. Neupert, the Health Officer of Wisconsin, presented a splendid discussion of the program from the administrator's viewpoint.

The exhibit at this convention has been a most popular one. Approximately 450 people have taken an average of two of the six tests available. Noteworthy is the fact that, although a few of the individual items have been criticised, almost everyone has expressed his enjoyment in taking the examination and has approved the technique.

Let us remember that this is a program of our own organization, the American Public Health Association, in an effort to help us solve the problem of intelligent selection of personnel. Understanding and support are required of each one of us to make this splendid effort a continuing success.

I for one would like to commend very heartily the very fine work that Dr. Long, Mr. Frasher, and other members of the staff of the Merit System Service are giving in this program.

CHAIRMAN ATWATER: Again it is a pleasure to see how the interests of the American Public Health Association have broadened to include an area which a few years ago was not represented in the Association structure.

Our next speaker is the representative of the Epidemiology Section, Dr. Thomas D. Dublin, who has recently become the Executive Director of the National Health Council in New York. He speaks for the Epidemiology Section.

DR. T. D. DUBLIN: In trying to gather my thoughts together in preparation for this presentation, I suddenly realized that by seeking the highest points I was losing sight of the mountain range, if you will, that these programs represented. The quality of the presentations was in my opinion, and in that of many others with whom I have spoken, unusually high. It would be difficult to single out any one, or, any few as particularly outstanding. The most impressive thing in this annual meeting, and particularly as it relates to the Epidemiology Section, is the broad perspective, the broad panorama which is now being included in the Section meetings.

It is particularly interesting to me to see how so many people from so many diverse fields are making significant contributions to the solution of problems which we have included in our discussion in the Epidemiology Section: men from the laboratory, from the field, from administrative positions, all have come together in this Section and have contributed a multiplicity of perspectives to our understanding of the problems which are under consideration. At the first session on influenza, a large group of individuals, six different groups of workers, each representing a different part of the country, a different laboratory, a different area or field of investigation or administrative problem, in fact, even a representative from the international field, attempted, and very successfully, to throw light upon this very difficult and important problem.

Similarly, in our concluding session this morning we considered a new disease, or rather, a disease just recently recognized in this country, that of "Q" fever, an infection which in a very brief period of time has been widely and carefully studied. It is, I think, a source of real gratification to see how so much has been learned of significance in dealing with a disease, unrecognized and unfamiliar to most of us, in a relatively short period of time.

In these and other sessions, the laboratory man, the field worker, the admin-

istrator, the educator, and various others had significant contributions to make to the solution of chronic disease problems, cancer, diabetes, tuberculosis, histoplasmosis, the dysenteries, air-borne infections, syphilis and gonorrhea.

In summary, I would say that to me the high light of this Section was not only the unusual quality of the presentations and their broad perspective of epidemiology, but rather that these sessions, particularly this year, emphasize how important it is for us to meet at least annually to merge our interests, to discuss common problems, and to throw all of our energies and efforts into the study and the working out of methods for the control of those disease and health problems with which we are all confronted.

CHAIRMAN ATWATER: The next speaker is Dr. Vlado Getting, well known to you as Massachusetts State Commissioner of Public Health. In this connection he speaks in his capacity as Chairman of the Committee on Eligibility of the American Public Health Association.

DR. VLADO GETTING: The Committee on Eligibility consists of one Fellow from each Section plus a chairman elected by the Executive Board. Its function is to pass upon the applications of Fellows, of members, of Life Members, to pass upon the application of state societies which wish to be affiliated with this organization, and to make recommendations relative to the election of Honorary Fellows.

Our organization has grown this year very satisfactorily. There are now over 11,500 members and Fellows. This year we have added 164 Life Members. This was as a result of the fact that the new Life Membership dues became effective January 1. Even at the present rate of $200, Life Membership is a bargain, and I recommend it to each of you, especially for Fellows, who receive a 6 per cent yield on an investment for the first 17 years, after which it costs them nothing.

Two hundred and fifty new Fellows have been added to our list. The number of new members has not been quite as large as previously, but over 1,200 were added. Two new state societies have become affiliated with this organization, those of Minnesota and Washington.

Finally, the committee had the privilege of recommending for election as Honorary Fellows three well known individuals: Dr. V. Mary Crosse of England, known to all of us for her work on prematurity; Dr. Brock Chisholm of Canada, now Director General of the World Health Organization; and Dr. Karl Evang of Norway, who is chief of the Norwegian Public Health Service.

The Committee on Eligibility wishes to call to the attention of qualified members that they should seriously consider becoming Fellows and taking advantage of the privileges offered to Fellows.

CHAIRMAN ATWATER: Our next speaker, Mr. James Gibbard, who is Chief of the Laboratory of Hygiene, Department of National Health and Welfare, Ottawa, Canada, is a seasoned representative of the Laboratory Section.

JAMES GIBBARD: I think one of the highlights from the standpoint of the laboratory workers has occurred within the last hour or so, and that is the number of representatives of other Sections who have seen fit to refer to the work conducted by the laboratory group.

One of the difficulties that I am faced with at the moment is that we feel it is rather difficult to evaluate adequately the highlights of any particular stage. In that connection one might refer to an occurrence some twenty-five years ago when this Association met in Boston, at which time Dr. R. L. Kahn presented his technique for the Kahn test. Although not present at that time,

I am informed that it created considerable discussion, but one wonders whether it would have been referred to as a highlight of the 1923 meeting. How can we accurately predict where emphasis should be placed at the present time?

Some of the papers that have been presented are of highly technical nature, and most of us are in no position to evaluate the significance of such work. I think, however, it is rather remarkable that the Laboratory Section and laboratory workers in general have become involved in so many other fields of activity. You have heard references to "Q" fever which in our estimation was one of the most important presentations at this meeting. You have heard references to problems in nutrition and the studies on infectious diseases—again, with participating laboratory workers.

If one were to take an impression of the highlights, or rather, an impression of interest at this meeting, it would be that the laboratory workers as a group are vitally concerned and, to say the least, a bit worried about the effect of health grants for programs not primarily in the laboratory field. They all visualize a tremendous increase in demands for work in the laboratory and I trust that workers in other public health fields will not forget the important role that the laboratory must play, has played, and we hope will continue to play, and the necessity of supporting and continuing efforts in the development of high standards of work. Funds must be made available for the conduct of laboratory and research work if other wider problems are to be solved.

CHAIRMAN ATWATER: Have you any prediction as to those things which twenty-five years from now will look as important as the Kahn test for syphilis looks in 1948?

MR. GIBBARD: As a guess, one would feel that probably the application of radioactive isotopes in the elucidation of problems of infection, immunology, and nutrition. Perhaps we will look back in twenty-five years and wonder at the importance of the paper that was presented on that subject at these meetings.

CHAIRMAN ATWATER: The Laboratory Section next year will celebrate its 50th anniversary. It is one of our senior groups and we look forward to another good program.

The speaker for the Health Officers Section, Dr. Herman E. Hilleboe, has been called home on an emergency and his place has been taken by Dr. William A. Brumfield, Jr., his first deputy.

DR. W. A. BRUMFIELD: I shall speak on one point discussed at the Health Officers Section, namely, the question of recruitment of personnel and personnel administration, because I feel this is by far the most important problem that is facing the public health administrator.

A panel on this subject was held on Tuesday afternoon. I shall give you briefly the points of agreement of this panel. First, it was agreed that personnel administration is a specialty and in every large health organization, certainly every state department and large municipal or county health department, there should be a special office of personnel administration, this office to be directed by a well trained and competent personnel administrator.

It was agreed that the services of the officers in these large organizations should be made available to smaller organizations within the framework of the state so that the services of these specialists could be available for those organizations in which such services would not be practicable on their own money.

It was agreed, secondly, that recruitment of personnel is one of the most important problems confronting health officers today. This recruitment of personnel is not confined solely to trained

personnel who can be put to work, but it also relates to persons who may be recruited for training, and who eventually can be put on the job.

It was agreed that the low salaries which are offered in health positions is one of the foremost reasons for the inability to recruit and train personnel at this time.

Third, the matter of selection of personnel: It was agreed that the merit system should be followed in so far as possible in the selection of all types of professional personnel: nurses, health educators, engineers, and physicians; and that examinations of both the written and oral type are applicable to the selection of personnel.

It was also agreed at this time that we should not limit examinations to groups of persons who are competing against each other, but should set up a system of continuing examinations which would permit individuals to be examined, or to compete against a standard.

It was also agreed that training of personnel should not be limited to the schools of public health or other types of institutions giving training to professional personnel in the field of public health, but that in each of the health departments there should be established an inservice training program which will provide refresher instruction to personnel in the organization.

Fourth, it was agreed that conferences between members of the staff are extremely important in the maintenance of morale in the organization and that such conferences should be held by the chief of the service at regular intervals and should be held in such a manner that the personnel from top to bottom could discuss the problems which confront them in order to get such problems solved.

It was agreed, fifth, that provisions should be made in all health organizations for increases in salary of personnel as they become more experienced and therefore more valuable; also, that, wherever possible, provisions for promotions should be made in order to keep competent people on the job.

And, last, it was agreed that when one had completed his work in the department and was eligible for retirement, or was forced to retire, provision should be made for a retiring annuity which would permit him to retire gracefully.

CHAIRMAN ATWATER: We shall now have a few words from a representative of the Committee on Administrative Practice. Dr. Wilton Halverson of California is chairman of that committee, but he had to be in Geneva this week for the meeting of the WHO Executive Committee. Dr. Roscoe P. Kandle, Field Director of the American Public Health Association, New York, will summarize the affairs of the committee.

DR. R. P. KANDLE: One of the things that struck me about the work under the C.A.P. is that the tempo and variety of interests and products of public health remind us that it is still a vigorous adolescent. I would like to remind you that the C.A.P. is composed of 150 of you and your colleagues who work very hard throughout the year, that there are many seeds sown during each session which germinate rapidly and grow most extensively. It is not just an annual meeting and then another meeting next year. There is a continuity in the growth.

One of the efforts of this committee is through its Subcommittee on Local Health Units. The National Health Council carries most of the action program now and, in spite of the trouble we have with regard to personnel, we are getting additional health units. For example, Indiana now has passed its first referendum. Admittedly, the campaign by Dr. Haven Emerson, Chairman of the Subcommittee, so well con-

ducted to extend health units, does aggravate the personnel recruitment problem, but I remind you of the citizens' support and interest, which is being gained by this campaign. It emphasizes the need for better salaries, and salaries *are* advancing in public health.

Evaluation of health practices is a tough discipline, and not a very pleasant discipline. Ofttimes it disturbs our complacency and upsets some of our choice illusions. Yet, 187 health units throughout the United States and Canada filled out the *Evaluation Schedules* this year and submitted them to the Association for appraisal; and a great many others used the schedule without formally submitting it.

Massachusetts, California, and Pennsylvania courageously requested extensive administrative studies at the state levels. Massachusetts and California have made significant use of these studies. The Pennsylvania study is just now being completed and we have good reason to believe that the Commonwealth of Pennsylvania means to make similar progress in providing better public health services.

The Engineering Group, a subcommittee under the Committee on Administrative Practice, has developed and distributed an *Evaluation Schedule* for sanitation, which is of great interest to everybody in the environmental sanitation field and is being quite widely used already.

A similar kind of special schedule is being prepared by the Public Health Dentistry Subcommittee, and we look forward to that with a great deal of interest.

In the technical field we cannot overlook the fact that a five year study group on multiple antigens is bringing out a report which was discussed yesterday and which will be of intense interest to every health officer and epidemiologist administrator in the field.

The Iodized Salt Bill in the House of Representatives in Washington was rejected in committee, and it got nowhere. In spite of frustrations, however, that committee continues to work with amazing persistence and patience, and they provided us with one of the most interesting of the scientific exhibits, which I hope you saw.

One of the things that are coming out of the Study Group under the Subcommittee on Evaluation of Administrative Practices is the statement on control of typhoid carriers which will be of good service to all health officers.

Just to add to what Dr. Francis said about the control of communicable diseases, there was a small but very important study group that worked all of last week-end and are going to bring us what looks to me to be one of the best things that have happened for some time, a report which clarifies the knotty problem of streptococcal infections and scarlet fever.

Accident prevention through health departments is going forward, and we had a good exhibit on that point by the National Publicity Council.

The important study of Public Health and Bedside Home Nursing Services was published last January. The Cost Study that began in 1946 in Public Health Nursing is bearing real fruit and getting more active every month.

You know a great deal about the Subcommittee on Medical Care, and I am sure you are well aware of their activity, through this Annual Meeting program. One thing I would like to point out is the joint committees, studying problems in medical care. Let me pay particular tribute to the one which Dr. Ellen Potter now heads, the joint committee on chronic diseases which has among its members representatives of the American Hospital Association, the American Medical Association, the American Public Welfare Association, and the A.P.H.A. They have worked long and hard this week.

EVELYN DUR

So we are making progress through this Standing Committee and I think we can count on the C.A.P. to deliver more goods.

CHAIRMAN ATWATER: Our next speaker represents Public Health Education, Dr. Granville W. Larimore, Director of the Division of Public Health Education in the New York State Department of Health.

DR. G. W. LARIMORE: There are three points in the Health Education Section program specifically which I would like briefly to call to your attention. The first of these is a realization on the part of public health educators of the necessity for what we have come to call "the techniques of community organization" for achieving many of the objectives of present-day public health programs. As we shift to the chronic disease problems and into those problems which are individual in nature, which require the active coöperation of all individuals, we face the need for people to solve their problems for themselves and the necessity for greater and greater concentration on these techniques.

This was brought out in the *Journal* in a paper by Dr. Turner, and also by papers concerned with Public Health Councils by Dr. Ferree and Mr. Lifson and others. The health council does represent a very effective technique for community organization for health within the community.

In Dr. Ferree's paper there was a little verse which seems to me to epitomize what a health counsellor in a community organization can do. I would like to read it to you:

> A horse can't pull while kicking.
> This fact I merely mention,
> And he can't kick while pulling,
> Which is my chief contention.

The second highlight of our session was a realization on the part of health education of its responsibility in the inservice training of public health personnel. We feel not only that public health education has a role in selling the health departments to our staff through programs of orientation, but also in improving the skill of our workers through on-the-job training, particularly in these days when personnel shortages are critical and we must make the best use of the personnel that we have.

The final point I would like to bring to you is the paper which Dr. Iago Galdston of the New York Academy of Medicine gave on "Motivation in Health Education." What is it that makes people have health habits, and how can we influence good health habits and how can we influence behavior toward achieving better health habits? Dr. Galdston quite frankly took health education to task for its emphasis in the past, and he feels—and I feel that we must agree with him in part, at least—that facts alone will not necessarily motivate people to achieve better health.

He refers to older techniques as "exogenous motivation." It tells people what to do, and there is nothing people resent as much as such instruction even if they are faced with death. We realize that "exogenous motivation," this business of merely presenting facts that are not related to the individual's own activity, is likely to fail.

The individual wants to eat, to move, to rest, to serve his body's needs. When he is a little boy he wants to grow big and strong and to be able to do things: to run, to play, and to acquire skills, to be an athlete, and so on. Then when he is a young man or woman he wants to be attractive, to be liked, to be popular, to have friends, to advance in his or her studies or work or ambitions. When grown older in adulthood he will want love, sexuality, marriage, and a home and children.

People will want these and many

other things, but they will not want health *per se,* that is, health pure and simple, unless they are hypochondriacs.

If we are going to teach health and influence behavior and develop good health habits, our teaching must be geared not to teach health *per se,* but to teach the individual how to attain his immediate goal. This Dr. Galdston designates as "endogenous motivation."

CHAIRMAN ATWATER: The spokesman for the Vital Statistics Section is Dr. Forrest E. Linder of the World Health Organization.

DR. F. E. LINDER: Statisticians like to use statistics. One important fact about our Section this week is that we are now forty years old. Forty years is not an age of infancy nor an age of senility, it is an age of maturity, and I think the maturity of the Section can be demonstrated by one fact: of five sessions which the Section held this week, four were in collaboration with some other unit of the A.P.H.A. or some related organization.

This maturity shows that the statistician is more and more coming to fill his proper role as an active collaborator with all the other health activities to which he can make a contribution. I cannot mention all of the twenty-five excellent papers that were read at these sessions, but I would like to point out two things that I think may be of particular interest to you.

One of these refers to the standardization and revision of the *International List of Causes of Death.* You have known that for a long time there has been an international coöperative effort to attempt to standardize the statistics on mortality. This new revision, which is a radical departure now incorporates many more titles arranged in such a way that the same list can be used equally well for mortality and for morbidity.

The statistician is going to have many headaches in adopting this list, and when the list is put into use we are going to have to explain to all of you many curious and difficult influences upon time trends. But after that difficult period is over I am sure that we will be on a new road for laying much sounder factual bases for the type of statistical data which public health workers need.

One other point in our Section I think is worthy of mention in particular, but I am a little timid about mentioning it. Since last election day statisticians do not boast too much about their sampling activity and about their polling activities. Nonetheless, if medical science stopped whenever it made a spectacular failure, or whenever its scientific concepts and advice were utilized for commercial gain, it would have stopped long ago. The science of statistics does not propose to stop at this time, and for that reason we are thinking and studying and trying to find out how the techniques of sampling and the techniques of statistical surveys can be applied to the problems with which you are all concerned. I think that before many years you will find we are making a contribution to that field which you will all find invaluable.

CHAIRMAN ATWATER: The spokesman for the Dental Health Section is Dr. Walter J. Pelton of the U. S. Public Health Service.

DR. W. J. PELTON: This year we public health dentists made great effort to plan our program so that each speaker or each group of speakers would make a contribution to the total program of the American Public Health Association. Our first theme was nutrition, diet, and dental caries, which I am sure we have not heard the last of yet.

The outstanding paper on "A Method of Evaluating Dental Programs" at our meeting with the American School Health Association was in reference to

the method that Dr. Kandle had in mind when he referred to the evaluation of dental programs. I think in the near future the evaluation method that the C.A.P. produced will be a notable "first."

The cancer session which we held was rather important and we included the whole field. It marks a very definite departure in public health thinking in that dental programs are now associated with geriatrics as well as pediatrics.

In connection with caries programs a paper was presented which developed sparks, heat, and considerable argument. The topic of that paper was "The Use of Auxiliary Personnel in Dental Programs," the development of the idea of using a dental nurse as an assistant to a dentist operating on a patient's mouth.

The Section has been active in the last three or four years in getting out a book on *Public Health Dentistry*. I am happy to announce at this time that the Saunders Company predicts that the book will be published about January, 1949. At this time I would like to thank the members of the American Public Health Association, particularly the staff, and especially Dr. Atwater, for his guidance and help and assistance in preparing this material.

CHAIRMAN ATWATER: I am glad you can report that the volume on *Public Health Dentistry* is as near completion as this. This is a real achievement, and you are going to be proud of it. The next speaker represents not only the Section on Maternal and Child Health, but he is also a spokesman for the new Section on Medical Care created on November 10 by the Governing Council. Dr. Dean W. Roberts is the Director of Medical Services in the Maryland State Department of Health in Baltimore.

DR. D. W. ROBERTS: I am glad now that the new Section on Medical Care can take away the honor from the Dental Health Section of being your newborn. There are some, I believe, who feel that perhaps this is a premature delivery, but I believe the more than 500 individuals who petitioned for the creation of this Section, most of whom were previously non-members of the Association, will assure you that it is a full-term Section which most certainly will not fall stillborn but will be lusty and vigorous in the days ahead.

In the program of the Child Health Section the highlight to me was a symposium on prematurity. There were two particularly excellent papers presented by Dr. Katherine Bain and Dr. Helen M. Wallace, but I would like to discuss the symposium as a whole.

The enormous importance of prematurity as a public health problem was well documented. This is the principal cause of infant mortality in virtually all parts of this country. About 6 per cent of all babies born are born prematurely. Over one-fifth of these die. In New York City 50 per cent of infant deaths are premature infants.

Throughout the country, particularly in New York, in Colorado, and Louisiana, we are seeing demonstrations of programs developing which, although they have not yet brought full answers, give promise of throwing a very considerable light on the problem of prematurity and what to do about it. We need to know what roles are played by economic factors, by nutritional factors, and by emotional factors associated with prematurity. Once we know more about the causes we can add more emphasis to prevention.

Even with our present knowledge we can intensify our program for providing prenatal care and adequate diet for pregnant women. We must work out good systems of care for the infants who are born prematurely, so often beyond the capacity of individual families, physicians, hospitals, or other single agencies. The program must involve the participation and coöperation of a

great variety of community resources; and will require public subsidy. The program must emphasize the essential nature of investigation of the homes to which the premature infant must return, preparing the home for the return of that infant, the teaching of the mothers so that when the baby is at home she will meet the needs of the infant with confidence.

Dr. Wallace very dramatically drew a picture for us comparing the facilities and the practices of a group of hospitals in New York City where little or nothing is done for the care of the premature infant compared with what is done in a modern premature infant center. The gap between what we do for premature infants and what we know we should do is vast, and we are only beginning to make a start to close that gap.

Moving from the Section on Maternal and Child Health, I would like to comment on one session that was sponsored by the Subcommittee on Medical Care.

That was a panel, a series of papers dealing with the quality of medical care. All too often proposals for medical care programs have so concentrated on the financing of medical care that the subject of the kind of medical care has been neglected, and we begin to feel that perhaps all we need to know is how to pay the bills. Such is not the case at all, and this symposium discussed a number of concrete administrative procedures which, if put into effect, can readily raise the quality of medical care.

The first of these papers was by Dr. Dean A. Clark in which he fully demonstrated the ways in which group medical practice will raise the quality of medical care.

A second paper was one by Dr. Albert D. Kaiser in which he showed us how regionalization of hospitals can be made functional. Every state that has drawn up a hospital construction program has dotted lines on maps showing presumed relationships between regional and general and subsidiary hospitals. In most instances those are just dotted lines. Dr. Kaiser showed us how those lines can be built into functional and effective measures of raising the standards of performance in hospitals.

CHAIRMAN ATWATER: Our next speaker is Charles L. Senn, Engineer-Director of the City Health Department Bureau of Sanitation, Los Angeles, Calif.

MR. C. L. SENN: The theme of our engineering Section program is well stated in the title of a paper by Dr. Henry F. Vaughan: "A New Look in Food Sanitation." First of all we tried to decide what we as public health engineers, are including in our engineering program. We heard from Dr. Winslow that the old engineer who devoted himself only to the use of those two weapons, control of water and sewage, is like the old soldier standing on guard at the gates of the city when the enemy has disappeared. We came to the realization that our enemy is now among the people themselves in their homes, and so we have started to develop some sort of a program that might attack that fundamental point. We talked about the old sanitary inspector, and we feel his day has passed. The profession must be elevated to be one which is respected as are others in public health.

The highlight of our session was to have an engineer, Dr. Abel Wolman, honored by receiving the Sedgwick Memorial Award. We heard from him how when he, as the only sanitary engineering representative of the World Health Organization, arrived at Geneva he found that, while they had included malaria control in their program, they had entirely omitted the broad field of environmental sanitation. However, they were pursuaded of the monumental

importance of that field and it was finally included as one of six major objectives.

We are mindful of the criticism heaped upon health officers and sanitation administrators for faulty restaurants, deplorable housing conditions, hordes of rats, and many other conditions and nuisances, and we feel that it is time that we took stock and developed the ways and means of combating those things and evaluating the work actually accomplished in sanitation.

To do that requires team work from the health officer, the nurse, the industrial hygienist, all working together. One demonstration of team work was presented in our morning session on housing— and here is a field where it was pointed out that the nurse, the planner, the builder, and the health officer can get together to evaluate what we consider perhaps the most important foundation of environmental health. There is need for coördination of our work with industry, and we are glad there has been established at the University of Michigan a National Sanitation Foundation where health people, educators, public health researchers, and industry can get together and work out problems so that some day we shall no longer have 30,000 different codes based on the "armchair" philosopher's ideas, but have codes based upon scientific knowledge and judgment.

I cannot end with a more fitting comment than the final paragraph of Dr. Henry F. Vaughan's paper in which he says: "Wisdom and statesmanship are vital to orderly progress in sanitation. The men of sanitary science are outnumbered in our health departments only by public health nurses. The nurse has done much to evaluate the quality of her contribution to the health program. The man in public health sanitation should do no less. In this endeavor he requires the sympathy and understanding support of every public health administrator."

CHAIRMAN ATWATER: The next speaker needs scarcely any introduction to you, Dr. William P. Shepard. He has many capacities in the Association, but most important for the moment is his capacity as Chairman of the Committee on Professional Education, one of the four Standing Committees of the Association, and on that I shall ask him to make a brief report.

DR. W. P. SHEPARD: I can do little more than give you an index of the many activities of the Committee on Professional Education which culminated for the past year, at least, at this meeting, in the hope that you may find your special interest in this index and read the reports in full as they appear.

As some of you know, the two reports that we presented to the Governing Council were approved, namely, that on the Educational Qualifications of Community Health Educators, a revision of Professor Turner's subcommittee's report of three or four years ago; and the report on Educational Qualifications of Sanitarians. They were approved by the Governing Council with very minor editorial changes made at our suggestion.

I thought you would like to know that among the additional revisions of existing reports which may be forthcoming very shortly is the report on engineers, the one on vital statisticians now practically ready, by Dr. Fales and Dr. Reed; and the one on public health nurses.

I thought you might like to know that we are authorized at least to tackle two new fields for such results as we may be able to obtain. One is the possibility of drawing up educational qualifications for non-medical administrators. They are variously called "administrative assistants," and by other titles. They are the executive assistants, the administrative assistants

of health officers and hospital superintendents, and of many health department bureaus. We are also authorized to investigate the possibility of developing a report on the educational qualifications of dental hygienists, and to prepare a report on veterinarians in public health.

Just a word about field training centers. The report of Dr. Gaylord W. Anderson's subcommittee two years ago, approved last year by the Governing Council, has now been worked over into a little less ideal, but a little more applicable and practical form at the special request of the newly incorporated Specialty Board for Preventive Medicine and Public Health, of which I shall speak in a moment.

I am sure you have been impressed, as we have, by the studies and reports made by our Subcommittee on Salary Studies. You have had for the first time now from the columns of the *Journal* more or less current data concerning salary arrangements in official and voluntary health agencies.

I am sure you appreciate the Merit System Service's splendid exhibit this year, and their very interesting job of selling at the panel discussion which they held yesterday. I have never seen a better job done, and we are hoping it may call this splendid and unique service even more fully to the attention of personnel administrators and health officials.

The accreditation of schools of public health remains about as is, except that we are planning to increase the stringencies of the criteria somewhat, not in such a way as to discredit or hurt any of the existing schools, but rather as an additional hurdle, we might say, for proposed schools which aim to come up to the standards which the other schools have reached. This by no means shuts the door to the organization of new schools of public health, but it does make a university stop to think how they may meet certain minimum criteria before they suddenly decide to embark on such a course.

Our Subcommittee on Personnel Administration has done excellent work and has brought to our attention more fully than before the special arts and sciences and skills required in this field.

We have a subcommittee wrestling with an extremely difficult task under the chairmanship of Professor Turner, trying to devise some method of accrediting masters' degrees other than the master of public health degree in health education. It is a long, intricate subject that I have not time to go into now, but a progress report may be expected soon.

The Board for Preventive Medicine and Public Health has been incorporated, and consists of Dr. Walter L. Bierring as chairman, Dr. Felix J. Underwood as vice-chairman, Dr. Ernest L. Stebbins as secretary-treasurer, and six other members. Its incorporation was necessary before we made application to the American Medical Association's Council on Medical Education. Whether or not our plans for issuing specialty certificates in the field of public health and preventive medicine materialize, hinges upon a hearing in Chicago next February, and until that hearing is held and we have a decision from that Advisory Medical Council, we shall not be able to accept applications for specialty board examination.

We have never faced a more serious shortage of public health personnel, and while this question is beyond the scope of the Committee on Professional Education, it is of great importance to the American Public Health Association. We need more people and better people.

CHAIRMAN ATWATER: Our next speaker will be Miss Margaret S. Taylor, Director of the course in Public Health Nursing at the University of Minnesota.

MISS MARGARET TAYLOR: It seems

to this reporter that the Public Health Nursing Section, in planning the activities at this conference, put into practice some of the most vital premises on which public health nursing is built, namely, that public health nursing, to be effective, must have in its practitioners expert family health workers. They must know how to function as members of the public health team. Therefore, only one session was devoted exclusively to public health nursing, and we were very happy to participate with other Sections, feeling that in this complex society, if we are to meet the needs of the family and to function effectively as public health workers, it must be through coöperative action.

Therefore, most of these comments will highlight the individual session on public health nursing with special mention of the pertinent highlights in one or two others.

The one individual session was concentrated on Ways of Increasing Nurse Expertness "through time, through better guidance, through better orientation, and inservice education through analysis of the cost of these for better service." The university, it was pointed out, was in a very strategic position to help meet responsibilities in this regard. It can do this by having its educational programs flexible and individualized to meet the backgrounds and needs of the student and also the public (the needs of the community), correlating closely theory and practice. It was pointed out that such a program was only possible when based on a thorough knowledge of the advances in basic nursing education.

One attempt to reach the former end in universities is through increasing the learner's participation in his own learning, and it is felt that this is one important way to increase professional responsibility and competence.

There was also a very interesting discussion on how the nurse could be trained on the job, the length and the extent to which this could be done. A particular highlight of this discussion was that there were two main functions of this inservice education. One was to help the person gain skills through actual participation in functioning as a family health worker, with concern not only for the individual but also for families as a whole and of the health of the communities. Another was to learn how to function as a member of a public health team. To realize that it was essential to do the second in order to accomplish the first, use of supervision here entered the discussion. Emphasis was given through the meaningful, practical suggestion that only through actual seeing and experiencing guidance and counseling and supervision can we have dynamic vital staff nursing work.

Then because we are a very realistic group, the session ended with a discussion of need for and a method of cost analysis. There are discussion groups going on all over the country right now at which it is hoped not only nursing leaders from voluntary and public agencies will participate but also health officers and other persons concerned with operation of public health programs. So far, one health officer has attended.

Just one or two brief highlights on other Sections. At the joint meeting with the Health Officers on Personnel Management, again it was stressed that every new worker should have a planned orientation experience early in his employment. This orientation should be not for any one exclusive group, but should include all workers, not just all professional workers, but all workers in the agency, both professional and nonprofessional, so that all could put the philosophy into action. To learn together helps us to understand each other and then to function better as a team. This must be continuous in the service education program.

There were two other matters which were mentioned in this session. The problem of transportation, a very real problem and a most difficult one, to date is unsolved. If a large part of the health department budget is spent for public health nurses, this transportation bottleneck must be solved and it needs more realistic analysis. For this reason rural areas are losing new public health nurses.

It was emphasized also that there is a vital responsibility resting on the administrator to have all personnel work as a unit with excellent *esprit de corps*. We need to find a tangible way to put it in action so that we do not just say we will plan together, but we actually do it. The old story of allocation of responsibility with administrative backing is more necessary than ever in the complex public health work of today.

Many other discussions brought out the great importance of a good referral system between all agencies and persons, such as hospital and community agencies, so that every patient in the community would receive continuity of care to the limit of community resource and therefore have a chance to get well, prevent relapse, and stay well. This is an area long given intellectual approbation but with too little actual follow-through in action to date.

CHAIRMAN ATWATER: Now, a word from the chairman of the Committee on Salary Study. Dr. William R. Willard, Associate Professor of Public Health at Yale, who has made a special study of this subject during the last year or more during which time he has been chairman of the committee.

DR. W. R. WILLARD: We are all agreed, of course, that we would like more money, and you have had reference before to the urgent problem of recruitment and to the holding of personnel in the field now, which is closely tied up to the salary problem.

The first thing in trying to get salaries raised is to know something about what is now being paid. Consequently, efforts have been made to get information on a nation-wide basis as to the present picture on salaries. We have been very fortunate in that the U. S. Public Health Service, under the direction of Mr. Donald Simpson, Chief of the Personnel Administration Unit, has now completed three salary studies. The first one last year, on the salaries of state public health workers, was repeated again this year and is just off the press. A gap of about nine months between the two studies has shown, Mr. Simpson informs us, an overall increase of 6 or 7 per cent in salaries during that nine month period. Of course, one of our friends reminded us that we really did not get increases of 7 per cent, but we actually lost about 7 per cent when one compares these increases with the cost of living.

There have been some other studies on salaries that are significant, those made by the state laboratories, by the Vital Statistics Section of the A.P.H.A. and by the N.O.P.H.N. They are all useful in giving information as to the salary picture, and I feel sure if these studies continue as now planned, in the course of time—and not too much time—we will have useful trends which will be of increasing value in our efforts to secure adequate compensation.

I would like to point out that salaries are related closely to the qualifications of the individual, to his experience, to the responsibilities that he holds, and it is rather difficult, as matters now stand, to compare salaries in one area with those in another because of unknown factors involved. Jobs are called by different names, and they carry different responsibilities and require different backgrounds, and in an effort to get more adequate information for comparison as well as for many other purposes, the subcommittee is giving some consideration to formu-

lating a study project by which we hope to get more tangible and concrete information.

I think you are all aware of the Clearing House on Salary Information that the *Journal* has carried. I think that has been useful. I certainly hope that you will submit information that you pick up, your own experiences and anything at all that you feel would be helpful for other people to know about in improving the salary picture. Certainly, Mr. Frasher and other A.P.H.A. members have done a wonderful job with their clearing house information as well as in other phases of the salary problem.

Now, we come to the last point. You may recall that some months ago the Executive Board of the A.P.H.A. made a recommendation of minimum salaries for public health physicians. There is a considerable feeling that those recommendations should be modified, certainly extended to include other groups. The force of the A.P.H.A. standing behind certain recommendations might be helpful to you and to other workers in increasing salaries.

Consequently, the committee has begun a formulation of such recommendations and if they are approved later on by the Executive Board, possibly you will have another weapon to help you.

I rather hesitate to predict that you will have increases in salaries during the next year. I certainly hope you do. If you do, you might consider putting some of it in life memberships of the A.P.H.A.

CHAIRMAN ATWATER: Our next speaker is Dr. Winslow, Editor of the *American Journal of Public Health.*

DR. C.-E. A. WINSLOW: Dr. Atwater, I think that up to this time and excluding from consideration anything that may happen in the next five minutes, I should be prepared to say that the high point of the convention was the panel discussion this afternoon.

Certainly, one of the high points of this convention has been the remarkable efficiency with which it has been managed, involving a great deal of work on the part of Dr. Cauley and Dr. Wilinsky and the rest of their committee and of the staff of the Association.

Another is the quality of the papers. I have been to a good many of these conventions, but I doubt if we have had an annual meeting at which the quality of papers was as high as these have been.

A third factor, I think, of importance has been the note struck by centering so many of the discussions this week around the story of Lemuel Shattuck and giving us a background and a vision for all that we have been doing.

We have, however, not only sound roots in the past but promise of brilliant flowering for the future. I think one of the best things that have ever happened to us has been the creation of the Section on Medical Care.

I think perhaps, to me, however, the highest point of this convention is one that has been brought to our attention this afternoon but possibly not sufficiently emphasized. That is, the work of the Standing Committees.

You have heard Dr. Getting in regard to the Committee on Eligibility, and Dr. Francis on Research and Standards, and Dr. Kandle on Administrative Practice and Dr. Shepard on Professional Education, but I doubt very much if many of you have any conception of what this Association, and the cause of public health, owe to these Standing Committees. These are not sitting-down jobs. Just think where we should be in public health without the report on *Standard Methods for the Examination of Water and Sewage,* and the report on *Standard Methods for the Examination of Dairy Products,* and the report on *Diagnostic Procedures and*

Reagents. Where should we be without the procedure for evaluating health services and the studies on salaries and personnel adjustment? Where should we be without the formulation of standards for the various types of health workers and for the procedure of accrediting schools of public health under Dr. Shepard's leadership?

I have had the good fortune to attend two of these committee meetings, which sat until 1.00 a.m. in each case. I was filled with admiration and with a deep sense of responsibility to between 300 and 400 people who are working throughout the year on development of standard procedures, and of methods which are absolutely fundamental to everything we do. I think that is a service which is more or less unique in professional societies in its extent and in its quality.

Now, just a word about the *Journal.* You know what the *Journal* is worth better than I do, but I want to say, in closing, one word on what I think Dr. Atwater and Mrs. Jay and the rest of our colleagues working on the *Journal* feel to be its primary and major functions. That is, as I see it, to tie together the thirteen Sections of the Association and the four countries over which its membership of 11,500 is now diffused. In all other countries except the British Empire, so far as I am aware, public health is essentially a branch of medicine. Here we recognize the medical health officer as our leader, but we conceive of public health as a social movement which includes a dozen professions, medicine, engineering, nursing, dentistry, nursing education, nutrition, etc., bound together in a single common cause, brothers and sisters in arms against a common foe.

The A.P.H.A. is not a melting pot in which diverse elements are fused into a single substance. That would be a very dull and deadly thing. This Association operates in quite a different way. It is a polarization of diverse groups and their coördination in a single task, each profession contributing its special knowledge and special accomplishments toward a single goal.

The organization of a dozen groups of independent specialists into a team devoted to the well-being of mankind is the supreme attainment of the American Public Health Association, and it is the major ideal of the *Journal* to play its part in that great task.

CHAIRMAN ATWATER: Thank you Professor Winslow and each of the other participants who, in an extraordinary way, have precipitated in a few words the opinions that they have about this program.

Many of the program papers will appear in the *Journal* and some in other publications. We will make them available to you as rapidly as possible.

Dr. Charles F. Wilinsky, who is President-Elect, is taking office now at the close of this annual meeting, and I will ask Dr. Wilinsky if he will close this Second Special Session, which is the last meeting of the 76th Annual Meeting of the American Public Health Association.

DR. WILINSKY: Dr. Atwater, distinguished members of the panel, and my good friends, the membership of the American Public Health Association, we in Boston have waited a quarter of a century for the happenings of the past week. Our regret is that you gave us so long a breathing period in which to prepare for the 76th Annual Meeting, and we earnestly pray that you do not keep us waiting so long again.

It has been a source of great joy, of great satisfaction to each and every member of the Boston Committee, to make it possible for you to spend what we hope has been a pleasant five days, but we are particularly delighted with the reactions which we are receiving from all sources as to the content of the scientific program.

Those who know Bostonians, and we acknowledge our frailties and our shortcomings, agree at least that we have tried to be hospitable, and we had no fears but that everyone would do all he could to make you feel at home. We are mindful, of course, of the limitations of our meeting facilities. We were troubled about the headquarters at Mechanics Building for the meeting, and, therefore, we only hoped that difficulties would not be too great and would not impede the scientific deliberations and the opportunities for the exchange of ideas from which the men and women and children of America would profit.

May I express for the Local Committee, may I express for the people of Boston and of New England, our very deep gratitude for your kindness in coming here to be with us. We hope that your stay has been pleasant. You have enriched us by being here, and you have stimulated us to try to strengthen our health service on what we may term local levels because of the inspiration we have received from your presence among us.

God bless you all.

CHAIRMAN ATWATER: The meeting is adjourned.

A New Look at Sanitation*

HENRY F. VAUGHAN, Dr.P.H., F.A.P.H.A.

Dean, School of Public Health, University of Michigan, and President, National Sanitation Foundation, Ann Arbor, Mich.

IT may come as a surprise to some of you that one steeped in the traditions of public health administration and sanitary engineering should possess the audacity to suggest a new look at sanitation. The colorful and impressive milestones spread over the past several decades emphasize the noteworthy accomplishments in the eradication of typhoid and other enteric infections through the improvement and extension of safe water supplies and the installation of sewerage systems and disposal and treatment plants.

It is fitting on this occasion to remind ourselves of the early studies and constructive actions instituted by those pioneer men of sanitary science who labored in Massachusetts. State participation and achievements in the advancement of community health have established historical benchmarks since the organization in 1869 of the first among the state boards of health. The creation of a Division of Sanitary Engineering in 1886, the oldest of all, constituted one of the first functional activities of the State Board of Health. The story of the able engineers, Goodnough and Weston, as well as the great contributions to sanitary science by the giants of the Lawrence Experiment Station, are too well known in the history of public health to require enumeration. Mills, Hazen, Fuller, Sedgwick, Jordan, Clark are names which symbolize the early struggles of the sanitary engineer and chemist with the realities of a healthful environment. Outstanding investigations showed the dangers of polluted water, the means of treatment and purification, followed by the brilliant contributions in the biologic studies of sewage treatment and stream pollution. These were followed by Sedgwick's impressive revelation of the conditions of market milk in Boston and subsequent introduction of bacteriologic supervision and ultimately pasteurization.

One need but turn to the pictorial review of *Health Practice Indices*,* 1943–1946 (pages 54 and 56) to be impressed by the noteworthy results in providing a safe water supply and an approved sewerage system in the 254 areas in 33 states with cities and towns of more than 2,500 population. Approved water supplies reaching 98 per cent of the population are found in more than half the areas reporting. There are but 20 areas in which less than 85 per cent of the population have approved water supplies. There are but 64 among the 254 reporting areas in which less than 75 per cent of the population is served with approved sewerage systems. A second glance at the *Indices* (page 62) discloses the significant fact that in 50 per cent of the 258 reporting areas more than 95 per cent of the bottled milk offered for sale is pasteurized. There are but 46 areas in which less than 70 per cent of the

* Presented at a Joint Session of the Food and Nutrition, Health Officers, Laboratory, and Engineering Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 11, 1948.

* Committee on Administrative Practice, American Public Health Association.

milk is pasteurized. Progress has been made, advances are noted in each succeeding edition of the *Indices*, and the results are extremely gratifying.

Now let us turn our attention to another chart in *Health Practice Indices* (page 60) and discover the percentage of restaurants, lunch counters, and taverns with approved sanitation and food handling facilities. Although this chart can only reflect reported practice, it is significant that 43 of 276 reporting communities claimed perfection—what a comfort to the harassed public health officer and his director of food inspection! More important, 52 areas furnished no information, and of 224 for which data were available only 50 per cent reported that 75 per cent of the food establishments had approved sanitation and food handling facilities—truly a sorry picture. But we are told that health education is the slogan of the streamlined health program, and that the printed word together with the spoken word and visual methods has been substituted for the outmoded practice of rigorous law enforcement. And so, with eagerness, we turn to the chart (page 61) which silhouettes the percentage of food handlers reached by group instruction programs. This chart relates to instruction in methods of food handling beyond that possible during inspections. Of the 276 reporting communities, only 13 report that 90 per cent of the food handlers are reached by group instruction; in only 48 areas are 50 per cent reached. Ninety-six communities have no group health education program, and for 62 areas no data were available. Truly these charts disclose the unplowed fields of environmental sanitation. Like other public health endeavors, the field of sanitation with emphasis upon clean surroundings, does not remain static but constantly undergoes adjustment to the living habits of people and to developments in business and industry and to the educational, research and other tools at the disposal of the healthmen.

All of the five charts referred to above portray items of major significance in the evaluation of community health services. These are among the 13 key items (red-black items) of the *Evaluation Schedule*,* 7 of which deal with problems of environmental health. The 2 remaining sanitation items will be found under milk pasteurization plant equipment and industrial health. Existing problems of food sanitation become more acute, and new problems are generated by changing modes of life. Men of sanitary science find themselves confused for want of factual data on which to establish reasonable standards and practices. Together with men of business and industry, they find themselves befuddled by the kaleidoscopic array of codes and regulations which impose requirements too little understood or unjustified for lack of basic scientific information. Sanitation, therefore, presents an illustrious history, a chaotic present, and a challenging future.

Every health program must have a philosophic background inspired by reason and understanding. The modern health department endeavors to help people to help themselves in the improvement of personal health and, thus, the improvement of community health. Public health is primarily the summation of personal health. The whole can be no healthier than the part. There are some services of personal and public health which government through its health department can perform better, others that the individual can do better, still others which depend upon a joint undertaking. In the handwriting of Abraham Lincoln on a scrap of paper found in the collection made public in July, 1947, the great emancipator expressed his views of the relationship of

* Committee on Administrative Practice, American Public Health Association.

government to the people. "The legitimate object of government is to do for a community of people whatever they need to have done but cannot do at all or cannot do as well for themselves in their separate and individual capacities. In all that the people can do as well for themselves, the government ought not to interfere."

For the past twenty years the health department and medical profession in Detroit have engaged in a program to activate the latent resources of medical practitioners in providing an ever-increasing service in preventive medicine through the office of the family physician and specialist. The private offices of physicians and dentists have become health centers, from which flow protective treatments for smallpox, diphtheria, and whooping cough, examinations for early tuberculosis and other departures from physical and mental health, studies for the discovery of infectious syphilis and gonorrhea, programs for the improvement of maternal and child health, utilization of accepted procedures in the fight against cancer and heart disease. There have been no public immunization clinics for diphtheria in Detroit since 1928. Nevertheless, 53 per cent of the children born in that city are known to receive the protective treatment by the time they reach their first birthday, 70 per cent by the age of 2. Sixty thousand children come to school each fall fortified with the report of a complete examination at the hands of the family physician. Parents have actually been sold the idea that preventive medicine is a necessity, a purchasable commodity, as essential to the family as food, fuel, clothing, and shelter. Services are available within the financial capacity of the individual family.

More recently the able health commissioner and his staff have embarked upon a plan to build the interests and resources of the manufacturer and the distributor of food products into a unified and homogeneous program, to serve the public by promoting and maintaining a high level of cleanliness in all food handling establishments, including hotels, restaurants, lunch counters, taverns, and food manufacturing plants. Industry must bear a responsibility in the promotion of satisfactory sanitation control. Industry should use competent, trained personnel for their own sanitation programs, and such programs should be carried on with the coöperation of health departments. While the provision for supervisory and educational service remains an obligation of the trained sanitarian employed by the health department, such service can never adequately replace the contribution to food sanitation which can be made by a health-minded employee. The occasional visit to a food handling establishment is no substitute for continuous supervision by the employee and by management. Wherever practical, industry should be encouraged to employ a qualified individual for sanitary self-supervision. It has been done in the milk field. It is highly desirable that all food handling establishments, regardless of size, have some specific person responsible for the sanitary condition of the establishment. Health education at maximum effectiveness must be interwoven into the fabric of the food health service and must be understood and lived by those whose actions and behavior we aim to influence.

The needs for cleanliness have increased as the social, business, and living habits of people have changed. Problems of food distribution and service have evolved with the ever-varying patterns of production and consumption. What is the program of food sanitation for this country? Are there 30,000 different programs, each conforming to the pattern of the local health jurisdiction? Every man of sanitary science has faced these new problems and has had to make deci-

sions. There are periods of confusion and indecision. The business man is confounded by the multiplicity of codes and regulations and by overlapping jurisdictions.

The National Sanitation Foundation is an outgrowth of an interest developed on the one side by the public health official, on the other by business and industry. It affords a common meeting ground to discuss problems of mutual concern and to dispel the veil of uncertainty and ignorance which enshrouds the progress of each group. Only through understanding contact with the public health agencies, industry, and business, is it possible for the Foundation to contribute toward the solution of the most current and pressing problems. Research in sanitation must be as unending as sanitation itself. Each new development points the way to the discovery of newer and better agents and methods. In sponsoring research and health education the Foundation has been fortunate in having the aid of an able Consulting Board *

* The Consulting Board includes: Mark D. Hollis,‡ Asst. Surg. Gen., U.S.P.H.S., Washington, Chr.; Herman G. Baity,‡ North Carolina University, Chapel Hill; Earnest Boyce, University of Michigan, Ann Arbor; Joel I. Connolly, Board of Health, Chicago; Lewis Dodson,† City Health Department, Denver; Ernest G. Eggert, Georgia Department of Public Health, Atlanta; V. M. Ehlers, Texas Department of Health; Francis B. Elder, American Public Health Association, New York; A. H. * Member Committee on Research
† Member Committee on Education
‡ Member Executive Committee.

and Committee on Research and Education. The Board was impressed by the fact that there had been little basic work done to determine some of the sanitary aspects of dishwashing and this became its first study.[1-4] Codes are found throughout the country requiring 2 to 3 minutes' exposure to water at 170° to 180° F. for all dish sanitization irrespective as to whether the work is done by hand or machine. Mallmann and his associates, as a result of studies supported in part by the Foundation, recommend a rinse period of 10 seconds at 170° F. for single tank dishwashing machines. They recommend a temperature of wash water between 130° and 140° F. with a time interval of not less than 30 seconds; the flow pressure of water should be not less than 20 lbs. per sq. in. They have developed a Surface Analyzer with test plates which measures washing efficiency in soil units. These findings and recommendations have been adapted to routine field work. Other studies aided in part by the Foundation include methods of measuring end results in utensil sanitization,[5, 6] methods for testing various properties of dishwashing compounds,[7] factors affecting the properties of quaternary ammonium compounds as sanitizers,[8, 9] methods for testing the efficiency of high temperature-short time milk pasteurization.[10] Analyses have been made of legislative requirements and sanitary practices indulged in by health departments.

Media are being developed for the dissemination and acceptance of recommendations emanating from research and educational studies so that the findings may be more widely known to both public health and industrial groups throughout the country. Noteworthy is the holding of the first National Sanitation Clinic[11] at Ann Arbor in June, 1948, which brought together for four days 400 authorities from industry and public health. The clinic dealt with twelve major subjects involving food distribu-

tion and service including (1) sanitation education, (2) sanitation supervision and administration, (3) eating and drinking ordinances and codes, (4) dishwashing, (5) detergents and sanitizers, (6) sanitary requirements and installation of food service equipment, (7) soda fountain and luncheonette equipment construction and installation, (8) food handlers' training program, (9) vending machines, (10) bars and taverns, (11) food protection, and (12) rodent and insect control. Out of the clinic came an increased respect of public health for industry and of industry for public health. Both were drawn together by mutual problems and mutual objectives. There was common and vigorous accord on the need for more effort by national, state, and local agencies to improve sanitation.

There should be a national sanitation program sponsored and planned by the U. S. Public Health Service, in coöperation with state and local health authorities. Industry as well as the public is entitled to know what the program of sanitation is for the United States. Generous appropriations have been made by Congress to support plans for the control of venereal diseases and tuberculosis, for cancer services, heart disease, and dental health. Funds are available for the elimination of stream pollution. However, the basic problem of completing the coverage of our nation with full-time local health units served by trained personnel and emphasizing the needs in public health nursing and sanitation, remains ahead of us. The constructive and positive aspects of health education and food cleanliness must be woven into the fabric of the local health department and made a prime objective of all food service industries. In no other manner can we expect to realize and enjoy the fruits of research and education in this field.

A national sanitation program may well embrace the following seven points:

1. *Trained personnel*—Provision for adequately trained and experienced personnel in the field of public health is an absolute necessity to gain proper respect for the sanitation movement. Healthmen have been criticised in the past, and will be criticised, as long as the liaison officer with industry remains the politically-appointed inspector in the local health department. The American Public Health Association through the Committee on Professional Education should define the terms of sanitary science, the duties and responsibilities of the public health engineer, the sanitarian, and the sanitary inspector. Qualifications together with acceptable nomenclature are essential to uniform practice. Industry and the public are entitled to know "What is a Sanitarian?" Is he a street cleaner who pushes a two wheeled cart, or is he a college graduate prepared to direct intelligently the health programs of industry and the health department? Should the men of sanitary science be trained in our great universities and schools of public health, concurrently with other personnel to be employed by full-time health departments? Possibly the leaders and supervisors should have an academic background in biology and public health, while the sanitary inspector with lesser responsibility may receive inservice and orientation training! At least there is no place in the picture for unqualified personnel; and public funds should not be available for the employment of political hacks in the name of public health. To employ such individuals engenders distrust and contempt both on the part of the public and men of industry.

2. *Research in sanitation*—A national program can and should be developed as a potent tool in the movement for better sanitation. There is a changing cycle in environmental health which has brought forth increased sanitation problems. Accordingly, appropriate research in the hands of qualified men in sani-

tary science should be promoted and supported in the field of food sanitation, and media should be developed for the dissemination and acceptance of such research by the public health and industrial groups.

3. *Sanitation education*—Education concerning sanitation is essential to help in measures for the improvement of health and the satisfactions of living as well as for the prevention of communicable diseases. Information may be made available through various media including (1) the spoken word, (group meetings, person-to-person, radio, television), (2) printed matter (newspapers, magazines, bulletins, newsletters, posters, car and bus cards, pamphlets, portfolio presentations for speakers, comics, cartoons), and (3) visual aids (photographs, films and slides, motion pictures, exhibits and displays). The channels of communication are innumerable. A national sanitation program would provide a clearing house for ideas, methods, and media, both old and new, for use in the development of sanitation education. There is need for a sanitation slogan, likewise a symbol, to emphasize the positive aspect of cleanliness. Possibly in this manner sanitation can be glamorized and removed from the dismal abyss of street cleaning and rat destruction.

4. *National sanitation clinic*—The pattern of a national sanitation clinic has already been established. However, this can very readily be altered and improved upon. Periodically, the major subjects of food sanitation should be reviewed by authorities from industry and public health. The questions which need answers fall into three classes: (1) those that can be answered by an analysis of research material available, (2) those that cannot be answered except by the process of best judgment based upon existing experience, and (3) those requiring additional research and study. The holding of regional clinics would do much to develop the scope and influence of such conferences by focusing the attention of industrial and public health groups upon the problems of sanitation.

5. *Testing laboratory*—The provision of an adequate testing laboratory is fundamental to research and the orderly progress of health education. The need has long been felt by both industry and public health people. Many of the current problems concerning new equipment and new products might have been settled long ago.

6. *Publication*—True, there are several journals in the field of sanitation at the present time but none successfully covers the field of environmental health. From industry, comes the demand for a single authoritative journal, the publication of which will obviate the need of keeping track of a number of journals in the health field which but occasionally contain contributions of interest to those handling food services and equipment.

7. *Textbooks*—With a view to sanitary practices, an analysis should be made of the various textbooks used in schools, and pamphlets and other material prepared for public consumption. There should be a substantial basis for public educational programs by schools, health departments, and other agencies. Every individual during the early years of life should have some appreciation of the whole subject of sanitation. Some young people may even choose to enter the profession of sanitary science and help fill the voids in the health department ranks. The task of industry is materially eased by the employment of personnel possessed of an appreciation of a subject which is materially a part of the job for which the individual is employed.

Wisdom and statesmanship are vital to orderly progress in sanitation. The men of sanitary science are outnumbered in our health departments only by the public health nurses. The nurse has done much to elevate the quality of her contribution to the health program; the

man of public health sanitation should do no less. In this endeavor he requires the sympathetic and understanding support of every public health administrator.

International Adoption of Principles of Morbidity and Mortality Classification*

W. THURBER FALES, Sc.D., F.A.P.H.A., AND IWAO M. MORIYAMA, PH.D., F.A.P.H.A.

Director, Statistical Section, Health Department, Baltimore, Md.; and Chief, Mortality Analysis Section, National Office of Vital Statistics, Washington, D. C.

ADOPTION by the First World Health Assembly at Geneva on July 24, 1948, of Regulations No. 1 carried to completion one of the tasks which were given to the Interim Commission of the World Health Organization by the International Health Conference held in New York City in June and July, 1946.[1] These regulations, which are to be known as "Nomenclature Regulations—1948," provide for the formal adoption, internationally, of the Sixth Revision of the *International Lists of Diseases and Causes of Death* as well as uniform procedures in the compilation and publication of morbidity and mortality statistics. In conformance with the constitution of the World Health Organization, the regulations will come into force for each member nation one year from date of adoption except for those nations which formally record rejection or reservations within that period.

For nearly fifty years the *International List of Causes of Death* has been used by an increasing number of national and other agencies in the compilation of statistics of causes of death. The Sixth Decennial Revision Conference, following past tradition, met in Paris from April 26 to 30, 1948, at the invitation of the French Government. The Conference marked the beginning of a new era in international vital and health statistics. It adopted a single comprehensive list of diseases, injuries and causes of death for use in the compilation of statistics of both morbidity and mortality. In addition, it recommended the adoption of a far-reaching program of international coöperation in vital and health statistics. Its recommendations were directed to national governments and to the World Health Assembly.

It will be recalled that the Fifth International Conference for the Revision of the *International List of Causes of Death*, held in Paris in October, 1938, requested the United States to continue its investigations of the "joint-cause-of-death" problem during the decade 1938–1948 on a slightly wider basis, in cooperation with other countries and organizations. In accordance with this resolution, the Secretary of State of the United States appointed the U. S. Committee on Joint Causes of Death in 1945. Representatives of Canada, Great Britain, and the Health Section of the League of Nations were included in its organization. The work and recommendations of this committee laid the basis for the sixth decennial revision and the adoption of international rules for clas-

* Presented before the Vital Statistics Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston Mass., November 9, 1948.

sification and tabulation. At the last meeting of the A.P.H.A., the U. S. Committee was awarded a Lasker Group Award for its accomplishments.

The adoption of the *International List of Causes of Death* has not led to complete international comparability of cause-of-death statistics. Aside from the questions resulting from differences in medical practice in different countries, the principal obstacle to international comparability has been the differences in procedures for classifying the main cause of death when two or more conditions were stated on the medical certificate of death. The problem was recognized by Farr from the very beginning of modern vital statistics, and his early letters to the Registrar General of England and Wales indicated the rules of selection that should be followed in such instances. At the First Revision Conference in 1900, Bertillon emphasized again the need for uniform rules for selection of the primary cause of death and proposed certain rules for international use. Similar rules were formulated by registration offices of other countries, including The Registrar-General's Office of England and Wales, although England did not adopt the *International List* until 1911.

In the United States, the Division of Vital Statistics of the Bureau of the Census appreciated that the uniform application of the rules required the recording of all decisions in order to establish precedents for similar combinations in the future. The division realized all along that the ultimate solution of the problem depended upon a painstaking comparison and study of individual cases, with thorough investigation of actual pathological relations. Neither the titles nor subtitles could be treated as units, but individual terms must be considered, together with the reporting habits of the physicians. These were the guiding principles by which the Division of Vital Statistics under Wilbur and Van Buren compiled the *First Index of Joint Causes of Death,* published in 1914, from the accumulated experience of our own national vital statistics. Subsequent editions have been issued which adapted the *Manual of Joint Causes of Death* to the various revisions of the *International List.* These manuals greatly aided the uniform and consistent classification of causes of death in this country, and their usefulness was recognized by many other registration offices.

A second obstacle to international comparability of cause of death statistics has been the lack of a uniform medical certificate. Various wordings for such a certificate have been tried and discarded over the years. The Committee of Expert Statisticians of the Health Section of the League of Nations studied the matter extensively and made specific recommendations in a report issued in 1925. The report recommended that instead of asking for the primary and contributory causes of death in that order, which had been the usual practice up to that time, the medical certificate of death should call first for the immediate cause of death (i.e., the disease, injury, or complication which caused death), and then the antecedent morbid conditions, if any, that gave rise to the immediate cause of death. Great Britain, whose representatives had been among the leaders in the deliberations of this committee, adopted in 1927 a medical certificate of death which followed closely these recommendations. The Vital Statistics Section of the Canadian Public Health Association also made careful studies of medical certification in the early 1930's and adopted in 1935 a medical certificate quite similar to the English certificate. The 1939 revision of the Standard Certificate of Death in the United States incorporated the essential elements of the League of Nations' recommendations; namely, asking first for the imme-

diate cause of death and then the antecedent causes, if any. However, the limited space available for medical certification on the U. S. Standard Certificate of Death precluded the inclusion of instructions given on the English and Canadian certificates.

All of these attempts to secure an adequate medical certificate of death have been aimed toward a better understanding, upon the part of certifying physicians, of the kind of information the vital statistician must have at his disposal in order to produce the most meaningful statistics of causes of death. From the time of Farr, our statistics of causes of death have been compiled on the basis of the disease or event (in case of deaths from external causes) that initiated the train of events leading to death. The rules of Bertillon were drawn up on this basis. Both the U. S. *Manual of Joint Causes of Death* and the English method followed the general rules formulated by Bertillon. However, the method of application of the rules in the United States and in England and Wales differed. In the United States, reliance was placed mainly on the joint-cause relationships given in the *Manual of Joint Causes of Death*, while the English based selection on detailed rules formulated on the basis of Bertillon's rules. Beginning in 1940, the selection of the main cause of death in England and Wales has been according to the doctor's entries on the medical certificate with the aid of a minimum number of rules for handling special cases.

The foregoing is a brief background of the work on joint causes of death up to the time the U. S. Committee on Joint Causes of Death undertook to study the problem. In their study, 10,048 microfilm copies of death certificates for Maryland and upstate New York were coded according to (1) the joint cause procedure as now followed in the United States, (2) a modification of this procedure which omitted from the primary cause assignment those terms reported as "other conditions" contributing to the death but not related to the immediate cause, and (3) the method used in England and Wales.

The study indicated that assignment of the main cause of death for this sample of death certificates agreed in 89 per cent of the individual cases whether assignment was made according to the usual United States procedure or by the English method. However, because of compensating assignments, the tabulated data showed an agreement of 94 per cent.

When the results of the English method were compared with those obtained by the modified United States joint-cause procedure, it was found that 95 per cent of the individual assignments of cause of death were in agreement. Compensating assignments increased the comparability to 97 per cent.

These results indicated that the arbitrary selection of the primary cause of death resulting from the use of the *Manual of Joint Causes of Death* as a classification tool was not primarily responsible for the apparent discrepancy between cause-of-death assignments and clinical interpretation of causes of death. The main source of difficulty appeared to be the American practice of considering every cause stated, regardless of its order and position on the medical certificate. It should be recalled that one of the objectives of the 1939 revision of the Standard Death Certificate was to separate the diseases and conditions directly leading to death from other contributing conditions of importance but not related to the disease responsible for death. This separation, however, had not been taken into account in our coding procedures.

Prior to the study, however, the U. S. Committee on Joint Causes of Death had recommended that the *International List of Causes of Death* be expanded so that a single statistical classification of diseases, injuries and causes of death

could be used in the tabulation of both morbidity and mortality data. The committee, recognizing both the physical impossibility and the lack of necessary experience for revising the *Manual of Joint Causes of Death* to accommodate the expanded base of the proposed classification, recommended against such a revision.

Further, the committee was of the opinion that the ultimate solution of the joint-cause problem in terms of more accurate and useful statistics could be achieved in other ways. Therefore, the U. S. Committee on Joint Causes of Death recommended to the Expert Committee of the World Health Organization (Interim Commission) and the Sixth Decennial Revision Conference that three fundamental steps be taken. These were: (1) the adoption of a uniform medical certificate of cause of death designed to elicit the necessary medical information, (2) the formulation of rules for the selection of the underlying cause of death, and (3) the institution of a program for medical students and practitioners to promote a better understanding of medical certification.

These recommendations were accepted in substance by both bodies. Regulations No. 1 adopted by the World Health Assembly provides for their acceptance internationally. For the first time, therefore, we have international acceptance of a uniform medical certificate of cause of death and uniform rules for the selection of the main cause of death. The international rules are, necessarily general in nature to the extent that they have applicability to all countries. The adaptation of these rules to take care of local peculiarities in reporting has been left to individual countries which will incorporate supplementary rules in coding manuals.

It is of particular interest to note that the international rules are not exactly new. They are largely but restatements of some of the general rules proposed by Bertillon in 1900. More particularly, they represent restatements of the special rules which the Registrar General of England and Wales has found necessary in the coding of causes of death. As we have seen from the study of the U. S. Committee on Joint Causes of Death, the application of the U. S. *Manual of Joint Causes of Death* and British rules to a sample of death certificates filed in Maryland and upper New York State show a surprisingly close correspondence. This close adherence is undoubtedly because they are both based on the same general principles.

The World Health Organization is publishing the new classification in a Manual which will consist of two volumes. The Manual will appear in English, French, and Spanish editions. Volume I will contain in addition to the Introduction, List of Categories and Tabular List of Inclusions, a section on medical certification and rules for classification and special lists for tabulation purposes. Volume II forms a comprehensive alphabetical index of diagnoses and conditions. For the first time, the English-speaking countries of the world will use the same manual, which will be a further aid to comparability of international statistics.

Implicit in the adoption of the new international joint cause procedures is the use of the international form of medical certificate. The new Standard Certificate of Death to be introduced next year in this country provides for the inclusion of this form of medical certification. The primary responsibility rests with the certifying physician to decide which morbid condition led directly to death, and to state the antecedent conditions, if any, which gave rise to this cause with the underlying cause stated last. The general rule for classification is to select as the cause to be tabulated, the underlying cause

which was the starting point in the sequence of events leading up to the direct cause of death. Exceptions to this general rule are incorporated in the *International Statistical Classification of Diseases, Injuries and Causes of Death* and in a coding instruction manual which the National Office of Vital Statistics will issue to amplify the international rules for use in this country. The primary purpose of such rules is to obtain consistency in assignments when required medical information is omitted or entries are inverted.

In adopting the new coding procedures, coding clerks should become thoroughly familiar with the Tabular List of Inclusions as well as the new rules. However, coders will find the procedure more interesting and satisfying since the logic of the assignment is seen more clearly than was frequently the case in coding by means of the *Manual of Joint Causes of Death*. In order to assist the vital statistics offices in making the transition between the old and new classification procedures, the National Office of Vital Statistics has, with the coöperation of the state bureaus of vital statistics, sponsored an orientation course on the new procedures. During the months of September and October, 3 day sessions of instruction were held in Washington, D. C., New York City, New Orleans, Chicago, Denver, and San Francisco, to which the state bureaus of vital statistics invited coders from various agencies. A more intensive training course will be offered during the coming year to states requesting such a service from the National Office of Vital Statistics if circumstances permit.

Another means of obtaining greater uniformity in coding practices is afforded by the comparison of cause-of-death assignments as made by the state bureaus of vital statistics and the National Office of Vital Statistics. These comparisons will be made, as in the past, on a sample of death certificates periodically for states requesting them, and differences in cause-of-death assignments will be reconciled. The purpose of these comparisons, however, is not to correct statistics but to point out errors in the application of the various rules.

Every revision of the international list or any change in coding procedures in the past has resulted in a break in the comparability of mortality trends. For many conditions, it is not expected that the problem of comparability with past experience would be any more serious than in past revision years. For certain causes of death, such as diabetes mellitus, where the change will be considerable, the statistics will provide more meaningful data by eliminating from primary mortality tabulations diabetes reported as a contributory cause of death. To assist in the evaluation of the effects of all such changes, the causes of death for 1949 are to be coded and tabulated by the National Office of Vital Statistics according to the old and new joint-cause procedures.

The new international classification of diseases, injuries and causes of death and the revised joint-cause procedure will open up great possibilities for improving the quality of cause-of-death statistics. However, there are a number of problems to overcome before its full possibilities can be realized. The most serious of these is securing improvement in the quality of certification. A step in this direction has been taken by including in the new standard certificate of death the international form of medical certification.

A great deal of time and effort will need to be expended during the coming year on these problems. The statistician should secure the coöperation of health officers in the task of promoting a better understanding by the medical practitioner of the medical certificate form. In the beginning, registration offices will have to do considerable querying in

order to be assured that the certifying physician has made entries in the correct order. The rewards of such efforts, however, will be great in improving the quality and the meaningfulness of our cause-of-death statistics. In addition, coding will be simplified when the entries on the certificates are made in the correct order. Fewer problems in the selection of the underlying causes of death will arise in these instances.

The expansion of the *International List* to cover causes of illness as well as causes of death opens up large opportunities for full utilization of the growing volume of morbidity data. Country after country signified their interest in a classification suitable for morbidity as well as mortality statistics. We must recognize, however, that the procedures for classification of mortality data have been based on years of experience. The handling of statistics of illness is relatively new, and, furthermore, the problems involved in their statistical classification are not so clear-cut.

Morbidity is far less definite than mortality. The occurrence of death is a discrete event, and the number of such events can be counted. An illness, on the other hand, varies from a minor deviation from normal health to the bed or institutional cases of chronic disease. For this reason, a cause of illness is not so easily defined as a cause of death. Furthermore, in many studies on morbidity, it is far more useful to study all the diagnoses involved rather than assign the illness to a single condition.

The Expert Committee of WHO recognized that the time had not arrived for laying down specific coding procedures in the handling of morbidity data. Instead, it called attention in its discussions of morbidity coding to the need for further studies of the problem. In the introduction to the *Code for the Tabulation of Morbidity Statistics* issued by the Medical Research Council of Great Britain there are suggested rules for the selection of the principal and contributory diagnoses, and in the introduction of the *Manual for the Coding of Causes of Illness* issued by the U. S. Public Health Service there is a further discussion of this problem with particular attention paid to the coding of multiple diagnoses. The next ten years should show a considerable progress in the development of procedures for the handling of morbidity data. In spite of the growing usefulness of morbidity statistics, mortality statistics remain the only body of disease statistics available universally for the study of many health conditions. Efforts to secure more accurate and reliable cause-of-death statistics will continue to be an important function of registration offices.

Plans for United States Coöperation with the World Health Organization in the International Influenza Study Program*

JAMES T. CULBERTSON, PH.D.

Division of Research Grants and Fellowships, National Institutes of Health, Bethesda, Md.

DURING the 4th International Congress for Microbiology held in Copenhagen in July, 1947, it was proposed that a program of international collaboration be initiated in the field of influenza. The overall purpose of the proposal was to set up the machinery necessary to protect the world population in so far as feasible against recurrence of another disastrous pandemic of influenza such as was last experienced in 1918. In September, 1947, the Interim Commission of the World Health Organization recommended that an International Influenza Center be established under Dr. C. H. Andrewes at the National Institute for Medical Research in London to study and analyze newly isolated strains of influenza virus, and advised that all nations set up organizations to collaborate with that Center. Subsequently, on December 4, 1947, Dr. Andrews addressed a letter to the Surgeon General of the Public Health Service, specifically inviting the participation of the United States in the coöperative program.

The thought behind the original recommendation of the Interim Commission was that, if the suggested machinery for promptly isolating new strains of the virus from outbreaks of influenza were to work smoothly, a vaccine effective against the particular strain of virus which is potentially able to cause a pandemic of influenza would be available for use before the disease itself had spread extensively. For example, under ideal circumstances, if such a strain were first isolated outside the continental United States, it could be incorporated in commercial vaccine and be available for protection of the population of this country before the disease had reached these shores. Or, even, if the strain were isolated in one corner of this country, it could be made available in commercial vaccine before the disease had extended over the entire nation. Admittedly, these examples ignore existing practical limitations in vaccine production which cannot easily, if at all, be resolved. Nevertheless, the peril to the nation and to the entire world of a recurrence of a pandemic of influenza is so great that almost any steps would be justified which, in the minds of authorities, might avert such a disaster.

Dr. Andrewes' letter inviting the United States to participate in the World Health Organization influenza study program was referred by the

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

Surgeon General of the Public Health Service to Dr. R. E. Dyer, Director of the National Institutes of Health, who, in turn, passed it on for advice to the Virus and Rickettsial Study Section. That body, which includes several of the nation's leading authorities on influenza, formulated at its meeting on January 26, 1948, the following recommendations which were later transmitted by Dr. Dyer to the Surgeon General:

> The Virus and Rickettsial Study Section is in hearty agreement with the concept of the World Health Organization to obtain information as to world-wide occurrence of influenza and the properties of strains of the viruses.
>
> The organizations in the United States, such as the Influenza Commission of the Army Epidemiological Board, which have, since 1941, maintained a continuous interest in these problems, have established listening posts, laboratories, and a Strain Study Center which have already demonstrated the effectiveness of such a program.
>
> It can be anticipated that information and materials obtained by all these organizations will be made available to the World Health Organization.
>
> It is recommended that the Strain Study Center operated at present at Cornell University College of Medicine under the direction of Dr. T. P. Magill be maintained, adequately supported, and be designated the National Strain Study Center for the United States of America.
>
> It is also recommended that the facilities of the U. S. Public Health Service be utilized to the fullest extent in this connection and, if necessary, be expanded and coördinated with other existing organizations.
>
> It is suggested that a committee designated by the Surgeons General of the Army, Navy, Public Health Service, and Air Force, be empowered to implement the program.

Following the suggestion of the Study Section, a meeting attended by representatives of the Surgeons General of the Army, Navy, Air Force, and Public Health Service was held in Washington on April 23, 1948, to discuss the implementation of the influenza program within the United States. At this meeting, the recommendations of the Virus and Rickettsial Study Section were adopted essentially in their entirety. It was decided to build the program in the United States largely around the National Strain Study Center, and to utilize the existing facilities for investigating influenza, especially those under the Army Commission on Influenza. It was also recommended that an Influenza Information Center be established in the Division of Research Grants and Fellowships at the National Institutes of Health to administer the World Health Organization influenza program in this country and to serve as the liaison office between the International Influenza Center in London and the coöperating laboratories in the United States. Such an Influenza Information Center has since been set up and is now participating in the international program.

FUNCTIONS OF THE INFLUENZA INFORMATION CENTER

As it has been developed, the Influenza Information Center is to have three principal functions: (1) to serve as a clearing house in the United States for the receipt and dissemination of information regarding influenza and the virus responsible for the disease; (2) to coördinate the work of the diagnostic "watch stations" needed in the United States for the laboratory identification of cases of influenza and the isolation of new strains of the influenza virus; and (3) to aid in arranging conferences looking toward possible improvement of influenza vaccine by the incorporation of newly isolated strains of virus.

The most urgent and immediate responsibilities of the Information Center are related to the prompt reporting of outbreaks of the disease and the establishment of an appropriate series of laboratories which could be called on to supply laboratory service essential to the serological diagnosis of cases of influenza and for the isolation of the

virus responsible for these cases. These responsibilities will be described in brief detail.

REPORTING OF OUTBREAKS

The reporting of outbreaks of influenza should in large part be taken care of through the existing reporting channels of the Division of Public Health Methods of the U. S. Public Health Service. However, the explosive character of most influenza epidemics and their exceedingly rapid spread over extensive areas present admittedly serious obstacles which only time and experience can fully resolve. Furthermore, it is unfortunately true that many cases of influenza are not reported by local physicians or by health officers until outbreaks have already attained com paratively serious proportions. The laboratory identification of most cases of suspected influenza is seldom obtained, and reported outbreaks of the disease cannot in most instances be authoritatively described as caused by influenza virus. One of the major responsibilities of the Influenza Information Center, then, is the encouragement of physicians and local health officers to establish definitively the etiology of cases of respiratory infection suspected to be caused by the influenza virus. Steps are being taken to focus the attention of medical practitioners on the importance of influenza and the need for reporting outbreaks of the disease, through motion pictures, exhibits, and announcements concerning the influenza program.

On receipt of information by the Information Center that a significant outbreak of respiratory disease suspected to be influenza has occurred in a given community, the Center will alert laboratories in the region, asking them to carry out serological tests on patients for the presence of antibody against one of the known strains of influenza virus. Likewise, the laboratories will be asked to try to isolate the virus from these patients. Once the virus, if isolated, is identified, reports will be broadcast as to the nature of the etiological agent responsible for the disease.

DIAGNOSTIC SERVICE

In an effort to meet at once the potential need for essentially nationwide diagnostic laboratory facilities, it has been recommended that a series of strategically located laboratories in the United States be formally invited to participate in the program, these laboratories to be called on for service in their immediate localities as soon as an outbreak of disease suspected to be influenza is recognized. It is not considered reasonable to set up *new* laboratories exclusively for this diagnostic function. Instead, it is hoped that existing laboratories which are already equipped for general diagnostic purposes, or else existing laboratories which are presently engaged in research on influenza, can serve in the program, either on their own initiative or when requested to do so by the Information Center in the event of an outbreak of suspected influenza in their locality.

It is anticipated that, because of the simplicity of the technics involved (principally the agglutination-inhibition test), many laboratories could quite easily prepare to perform the serological tests upon patients with suspected influenza. On the other hand, only few stations could wisely attempt, in addition, the isolation of strains of the virus from fresh cases. Accordingly, it has been proposed that two levels of diagnostic stations be set up: No. 1 stations, for serological testing alone; and No. 2 stations, for serological testing *and isolation of virus*.

When a No. 1 station reports to the Information Center that it has noted elevated titers of influenza antibody for any outbreak of respiratory disease, the nearest No. 2 station will be asked to

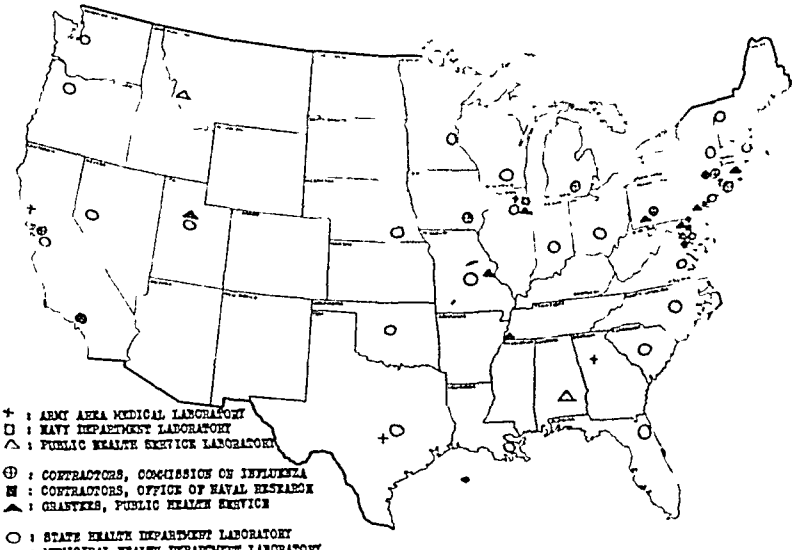

FIGURE 1. LABORATORIES IN THE UNITED STATES PARTICIPATING IN THE WORLD HEALTH ORGANIZATION INFLUENZA STUDY PROGRAM, UNDER THE INFLUENZA INFORMATION CENTER AT THE NATIONAL INSTITUTES OF HEALTH.

send into the affected area a team of investigators experienced in the technics of isolating the virus. The No. 2 stations would, presumably, be able to carry on the complete service, including the attempted isolation of the virus, whenever an outbreak of influenza or respiratory disease simulating influenza occurs in their own community. Once a strain of virus has been isolated, it would be sent at once for a complete antigenic analysis to the National Influenza Strain Study Center, which is under the direction of Dr. T. P. Magill, Long Island College of Medicine, Brooklyn, N. Y.

PARTICIPATING DIAGNOSTIC LABORATORIES

It is hoped that all diagnostic laboratories in the nation will, as opportunity permits, use their facilities to assist the influenza program. However, it has been deemed wise that a more formal invitation to participate in the program be extended to certain laboratories which are believed to be especially qualified because of their strategic location or because of their personnel. The laboratories which are to be formally invited to participate can conveniently be placed in three groups:

1 Those operated by one of the Services of the federal government

2. Those operated by local or state health departments

3. Those engaged in influenza research through support from the federal government

It is believed that the costs of participation in the program, so far as the laboratories of the first two of the groups just mentioned are concerned, could be met through the laboratories' own budgets, since the services involved would be part of the regular responsibility of these laboratories to the local, state, or federal governments. It is proposed that the laboratories of the third group would participate primarily on an emergency basis, and that, in an emergency, they would be willing temporarily to suspend their usual research activities, if necessary, to take on the diagnostic function. The funds originally supplied to these laboratories by the federal government for research purposes could, by administrative authorization, then be used to pay the costs of

participating in the influenza program. A list of the laboratories which have been formally invited by the Influenza Information Center to participate in the influenza program and which have accepted this invitation follows. The location of these laboratories is also indicated in Figure 1.

Laboratories Which Are Participating in the Influenza Study Program

Laboratories Operated by the Federal Government:

* Laboratories equipped for virus isolation *and* serological tests. Those not so marked usually equipped only for serological tests.

TRAINING OF TECHNICIANS

It is appreciated that some of the participating laboratories may desire to refresh one or more otherwise experienced technicians in the procedures for the serological tests or the virus isolation technics. Accordingly, provision has been made to train a selected number of such persons at the National Influenza Strain. Study Center, Long Island College of Medicine, Brooklyn, N. Y. Unfortunately, such training cannot be given by the National Influenza Strain Study Center itself until February 1, 1949. However, Dr. T. P. Magill, Director of that Center, has offered to suggest a conveniently located laboratory where suitable technical training can be obtained before February 1, 1949, to anyone who inquires directly of him.

THE NECESSITY OF COÖPERATION

The World Health Organization influenza program will succeed in its purpose to prevent the recurrence of a pandemic of influenza only provided that a high level of coöperation is developed and maintained among practising physicians, diagnostic laboratories, and the offices charged with administration of the influenza program. The first requirement of a successful program is that physicians report promptly to their health departments or to one of the participating laboratories all suspected cases of influenza. As significant outbreaks occur, the appropriate administrative office—which, in the United States, is the Influenza Information Center at the National Institutes of Health, Bethesda, Md.—will take the necessary steps through the coöperating diagnostic laboratories to identify the reported disease definitively. When new strains of influenza virus are isolated from cases, these will immediately be studied antigenically in the National

Influenza Strain Study Center. Eventually, appropriate strains of the virus which have been isolated will be considered for possible inclusion in commercial vaccine.

With good fortune—and always provided that it received the high level of coöperation which is essential to its successful prosecution—the influenza program as conceived may finally lead to the discovery of superior immunizing varieties of influenza virus. When available in commercial vaccine, these new strains of virus may significantly reduce the potential hazard from influenza which constantly threatens the population of the United States and of the world.

The Lasker Awards

An Editorial in The New York Times

President Truman aptly bespoke the sentiments of the entire nation when, in his message congratulating the winners of the 1948 Lasker awards, he conveyed "the gratitude of the Government and of millions of Americans for outstanding contributions to the health of our people." Indeed, the presentation of these awards to three scientists and four public health administrators at the annual meeting of the American Public Health Association in Boston should serve admirably to stimulate greater professional attention and public interest in the fields of the seven 1948 recipients.

It was particularly notable that Dr. Selman A. Waksman of Rutgers University and Dr. Rene J. Dubos of the Rockefeller Institute should be cited jointly for their studies of the antibiotic properties of micro-organisms found in the soil. Most of the present success of the antibiotic drugs stems from their work. To Dr. Waksman goes the distinction of having discovered streptomycin, in addition to 100,000 other micro-organisms. Dr. Dubos led a research group that first studied germ-killers from the soil and found the first antibiotic used chemically.

The Lasker honor for Dr. Vincent du Vigneaud, head of the Department of Biochemistry, Cornell University Medical College, New York, recognized his studies of trans-methylation and contributions to the chemistry of biotin and penicillin. Outstanding administrative achievements earned the awards given to Dr. Martha M. Eliot, associate chief of the United States Children's Bureau, and Dr. R. E. Dyer, director of the National Institute of Health at Bethesda, Md. The Lasker group award went to the Department of Medicine and Surgery, Veterans Administration, and especially Dr. Paul R. Hawley, its former chief medical director, and Dr. Paul B. Magnuson, Dr. Hawley's successor. The thousands of lives saved by the work of these distinguished leaders in the medical field stand as indisputable evidence of their right to the honors that have justly been bestowed upon them.

—*New York Times*, November 19, 1948.

Influenza in California During 1947 and 1948*

GORDON MEIKLEJOHN, M.D., AND HENRY B. BRUYN, M.D.

Viral and Rickettsial Disease Laboratory of the California State Department of Public Health, Berkeley,† and the Infectious Disease Laboratory of the San Francisco Hospital‡

THE behavior of influenza in California during the past two years has been unusual in several ways. In the first place there have been two statewide epidemics of influenza A, the first over the period from January to May, 1947, and the second from November, 1947, to February, 1948. The first outbreak appeared to originate at the Fairfield Army Air Base, shortly after the onset of the disease at Lowry Field in Colorado, and thereafter spread rather slowly and circuitously over the state, causing an explosive outbreak in the Fresno schools as late as May, during exceedingly hot weather. Scattered cases occurred throughout the summer, but it was not until late November, 1947, that community outbreaks of considerable size were reported. The first of these was in the area east of Los Angeles. By late December, the large urban areas of the state were affected, and cases continued to occur during the following two months. The overall incidence of the disease in both epidemics can only be roughly estimated. It was presumably low for the state as a whole, though high in certain communities.

A second feature which was of interest was the marked antigenic variation between the strains of influenza A virus isolated during 1947 and 1948 and strains isolated previously. This was in keeping with reports from other parts of the country.[1-3] The implications of this marked change are of considerable importance, from the standpoints of epidemiology and of control, and the present paper is concerned largely with the effects of this antigenic variation.

Various methods have been used to investigate the strain variation and certain of its effects: (1) The relationship of the new (1947–1948) strains to "old" strains has been studied by means of cross-agglutination inhibition tests with strain-specific ferret antisera. (2) The antibody levels against various strains have been determined in a group of healthy adults. (3) The distribution of titers in the acute phase sera and the increases in antibody for various strains in patients with clinical influenza have been studied. (4) The increase in antibody for various strains following vaccination with commercial vaccines has been measured.

MATERIALS AND METHODS

Virus Strains—The Influenza A strains used were PR8, Olson (Calif., 1943), Skopp (Calif., 1947), and Spirup (Calif., 1948). The Skopp strain was adapted to the amniotic sac of chick embryos following two intra-nasal passages in ferrets. The Spirup strain was isolated directly in the amniotic sac of

Cross-Agglutination Inhibition Tests with Strain-Specific Ferret Antisera

Strain	Ferret Serum			
	PR8	Olson	Skopp	Spirup
PR8 (Puerto Rico, 1934)	512 *	128	8	16
Olson (Calif., 1943)	128	512	128	128
Skopp (Calif., 1947)	8	16	256	256
FM1 (N. J., 1947)	32	32	256	512
Spirup (Calif., 1948)	16	16	256	256

* Numbers indicate reciprocal of serum dilution which completely inhibited agglutination of chicken erythrocytes by test strain.

chick embryos. Both were subsequently passed via the allantoic cavity and produced fluids of high agglutinating titer.

Agglutination Inhibition and Complement-Fixation Tests—These were carried out according to methods employed in this laboratory for some time and are described in full elsewhere.[4, 5]

Ferret Antisera—Animals were inoculated by the intranasal route with 2.0 ml. of either throat washing or allantoic fluid. Immune sera were obtained by bleeding the animals once or more between the 12th and 21st day after this single inoculation.

Human sera—Pre- and post-vaccination sera were obtained from various student groups at the University of California Medical Center and from employees of the Oakland City Health Department.* The majority of sera from patients with influenza were collected in the San Francisco Bay area. Others were submitted from various parts of the state to the Viral and Rickettsial Disease Laboratory for diagnosis.

RESULTS

Tests with Strain-Specific Ferret Antisera—The relationships of the new strains to older Type A strains were investigated in a series of cross-agglutination inhibition tests. Results are summarized in Table 1. It may be noted that: (1) the various 1947 and 1948 strains appeared to be similar in behavior; (2) the antisera for these strains had moderately high titers against a 1943 (Olson) strain; while the 1947–1948 strains were not inhibited to a significant degree by Olson antiserum; (3) that none of the 1947–1948 strains showed a significant cross in either direction with the PR8 strain. Stated in another way, the 1943 strain varied only in moderate degree from the PR8 strain, since there was cross-agglutination inhibition of considerable degree in both directions. Following further variation in 1947 there was a one-way cross with the 1943 strain, but no significant cross in either direction with PR8. Finally, no significant differences were noted between two strains isolated in 1947 (Skopp and FM1) and four strains isolated in 1948 (represented by Spirup).

ANTIBODY TITERS FOR NEW (SKOPP) AND OLD (PR8) STRAINS IN NORMAL INDIVIDUALS

The distribution of antibody titers for the two strains in a group of 159 individuals from the San Francisco Bay area is presented in Table 2. These

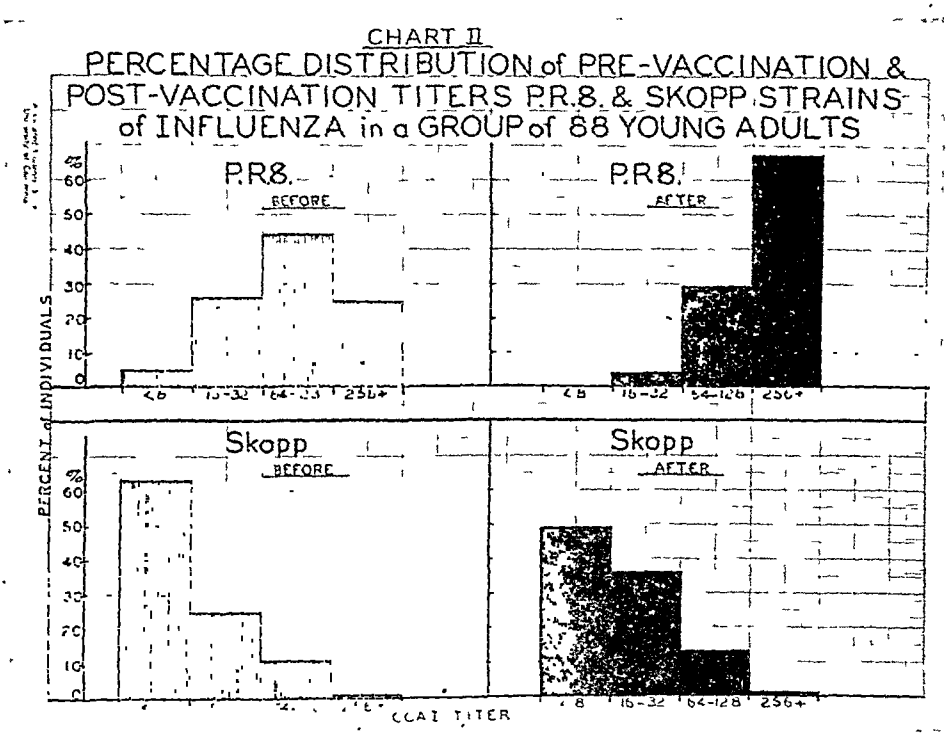
Percentage Distribution of Antibody Titers for PR8 and Skopp in Acute and Convalescent Phase Sera from 69 Patients with Influenza

C.C.A.I. Titer	PR8		Skopp	
	Acute	*Convalescent*	*Acute*	*Convalescent*
8 or less	39%	10%	97%	8%
16–32	48	32	3	62
64–128	13	36	0	29
256 or more	0	22	0	1
Number with Fourfold of greater rise in titer	45		62	



persons were bled during the fall of 1947, i.e., between the first and second outbreaks of influenza. The data show that antibody for the PR8 strain was widely distributed in adults and was frequently found in high titer. On the other hand, three-fourths of the persons tested failed to show levels of antibody for the Skopp strain greater than 8.

Antibody Levels in Patients with Influenza—For the purposes of this discussion the acute phase serum titers for the two strains are of most interest. Results are presented in Table 3. PR8 titers of 16 or more were found in the sera of 42 of the 69 patients. In contrast, only 2 of the 69 patients had titers of 16 when tested with the Skopp strain, the remainder falling in the groups with titers of 8 or less than 8.

The number of patients showing fourfold or greater increases in titer to the two strains is noted in passing, in order to bring out the fact that the experience of the past two years has emphasized the danger of relying on agglutination-inhibition tests using only the PR8 strain for purposes of diagnosis.

Influenza in California during 1947 and 1948

Influenza in California during 1947 and 1948

Failure to establish the diagnosis in 24 of the 69 cases would have resulted in this series. An apparent discrepancy between the number of patients with significant increases in titer and total number of cases of influenza is explained by the fact that in several instances the diagnosis was made by means of complement-fixation tests when agglutination-inhibition tests with both PR8 and Skopp strains had failed to show significant increases in titer.

ANTIBODY INCREASE FOLLOWING VACCINATION

The effect of this antigenic variation on the antibody response following vaccination was investigated in two experimental groups. The first group received an "old" vaccine which was prepared from PR8, Weiss and Lee strains. The data in Chart 1 show that there was a fairly good response to the PR8 strain. This is brought out by the shift of large numbers of persons from the low-titer into the high-titer groups. There was no comparable shift when sera were tested with the Skopp strain, the great majority of individuals remaining in the group with titers of 8 or less than 8.

The second group received a similar vaccine in which the Weiss strain had been replaced by a 1947 strain (FM1). Results are summarized in Chart 2. The response to the PR8 strain was exceptionally good. The response to the Skopp strain, which is antigenically very similar to the FM1 strain (Table 1), contrary to expectation, was disappointing. Half of the group still had titers of 8 or less than 8.

DISCUSSION

These studies emphasize the fact that influenza is not a static disease and that the influenza virus, which has shown marked variability in the past, continues to behave in an unpredictable man-

ner. The problems of controlling this disease have been affected by recent developments in a number of ways.

In the first place it has been generally held that almost all adults have signficant amounts of influenza antibody.[6, 7] This concept is based on work done with "old" strains, such as PR8, and, while it is true when one speaks of influenza in terms of the "old" strains, it is not true with reference to the strains isolated in the last 2 years. Relatively few of the individuals studied in these investigations had antibody for the new strain. It would appear that such a situation favored a rather explosive epidemic of influenza. Paradoxically, the reverse occurred. There were two outbreaks rather than one, and both were marked by a rather low incidence and continued over a long period of time. It is perhaps fortunate that this change in antigenic character was not associated with any obvious increase in virulence.

The uniformly low antibody levels in the acute phase sera of patients with influenza raises again the question of the relationship between antibody titer and susceptibility. Data acquired in 1943–1944 [8, 9, 10] supported the argument that such a relationship existed in the case of antibody to the current epidemic strain. The relationship was far less definite or absent with antibody to the PR8 strain. The data presented in this report show that in 1947–1948 infection often occurred in individuals with PR8 antibody titers even as high as 128. On the other hand, patients with influenza were in every instance found to have Skopp antibody only in very low titer, if at all, during the acute phase of their illness. A strong argument could be made that influenza was likely to occur only in individuals with a low Skopp antibody titer, were it not for the fact that in the group of normal individuals studied the proportion with high Skopp titers was not much greater than in the group of influenza patients.

A second effect has been to make it increasingly difficult to arrive at a serological diagnosis of influenza. The agglutination-inhibition test, which is generally used as a routine diagnostic procedure is relatively strain-specific,[11] and to be maximally effective should be run with strains isolated from the current epidemic. This is often difficult from the technical standpoint. Our laboratory, in the face of this problem, no longer uses the agglutination-inhibition test as a routine diagnostic procedure but has shifted to the complement-fixation test, which is not strain-specific when allantoic fluid antigens are used.

The third effect of importance has been on the potential value of vaccines. There is little doubt that in the past a considerable degree of protection has been provided by combined influenza A and B vaccines in epidemics of both influenza A [12] and B.[13, 14] However, it appears that the old vaccines do not produce satisfactory antibody responses to the new type strains and, in 1947, produced relatively little protection during an epidemic.[1, 2, 3] Even the incorporation of a new strain has not provided a completely satisfactory solution to the problem, if one takes the antibody response as a measure of increase of resistance. It would seem that the present problem could be clarified by further strain studies, particularly with monovalent vaccines, and that vaccines might be improved by the incorporation of other strains. There remains, however, the disconcerting possibility that further strain variation will occur, and that the future strains will be more unlike rather than more like the old strains.

SUMMARY

1. Two state-wide epidemics of influenza A occurred in California during the period 1947–1948.

2. Virus strains isolated during the two

epidemics were similar, but differed markedly from previously isolated influenza A strains

3. Antibody for the new strains was present in significant amounts in only a small proportion of 159 healthy adults tested in the San Francisco Bay area

4 The acute phase sera of patients with influenza were found to have antibody for the new strains only in very low titer

5 Poor antibody responses for the new strains were obtained with an earlier type combined influenza vaccine and with a vaccine containing a 1947 strain

6 Certain effects of the appearance of new strain types on the development of effective influenza vaccines are discussed

International Society of Hematology

The first formal Congress of the International Society of Hematology was held in Buffalo, N. Y., in August, with more than 700 persons representing 20 nations attending. This society is an outgrowth of the International Rh and Hematology Conference held in Dallas, Tex., and Mexico City in 1946. The next meeting will be held in 1950 in Cambridge, England. The officers elected for the next two years are as follows:

President: Sir Lionel Whitby, Regius Professor of Physics, Cambridge University, Cambridge, England

Secretary General (Europe) Dr Marcel Bessis, *Laboratoire de Recherche, Paris*

Secretary General (Western Hemisphere) Sol Haberman Ph D, Baylor University Hospital, Dallas, Tex

Secretary Treasurer, Dr Martin Hynes, Department of Medicine, Cambridge University

Effect of Rising Hospital Costs on Group-Payment Plans*

C. RUFUS ROREM, PH.D., C.P.A.
Executive Secretary, Hospital Council of Philadelphia

DISCUSSION of this question must recognize at the outset the basic functions of a group-payment plan for the hospital service. They are two: the *collection* of "payments" of money from large numbers of subscribers over a stated period of time; the *disbursement* of "payments" of money to hospitals which provide specific services to the subscribers during that period of time. The incoming group-payment must, in the long run, equal the outgoing payments to hospitals, with proper allowance for administrative expenses.

The main effect of rising hospital costs upon group-payment plans has been to intensify the problem of *"how to pay hospitals adequately and equitably"* for services provided to subscribers as contract-benefits. Sheer growth of membership has made this an important problem. The changing price level has brought it sharply to the attention of Blue Cross, the hospitals, and the people. No single formula is equally acceptable to all hospitals, whether the basis of payment be cost, established charges, average collections from non-contract patients, or a uniform negotiated rate for all hospitals.

The problems of rising costs are basically different for voluntary hospitals from those of proprietary and government hospitals. The proprietary hospitals serve a relatively small number of patients, each of whom is expected to pay the hospital's established charges. The other group serves mainly indigent cases; and patient fees are relatively less important than taxation as a means of financial support.

The commercial insurance companies provide cash allowances rather than service benefits in their policies. Consequently, reimbursement of hospitals for service is not an immediate problem for such organizations. Their contractual arrangement is to provide a certain number of "dollars" on behalf of policy holders. They are not responsible for contracting with hospitals to furnish stated amounts and types of service.

Before proceeding to a discussion of possible solutions, and an appraisal of prospects for their success, I would like to review the present situation of American hospitals, together with certain events and trends which have made voluntary hospital economics what it is today. The analysis and history will deal with services, costs, and financing.

HOSPITAL SERVICES AND COSTS

The replacement value of our 6,300 "registered" hospitals exceeds $6,000,000,000, as compared with scarcely $3,000,000,000 in 7,000 institutions 20 years ago. Some hospitals have disappeared. A few new ones have been organized. Many have been reorganized. The growth in value has resulted

* Presented before the Medical Care Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

from an expansion of existing hospitals and a substantial rise in the general price level.

The annual national hospital bill is estimated at about $2,200,000,000, which is slightly more than one per cent of the estimated annual national income, and more than twice the costs of service in 1928. Private resources are the main income for hospitals treating acute medical and surgical cases. Government hospitals provide most of the patient-days of care for mental and tuberculosis cases.

The total annual hospital bill has increased through the influence of several factors: the higher general level of prices, the increased number of people hospitalized, and the greater number and variety of services provided. Hospital wages are now approaching the amounts paid in other fields of employment.

Cost per inpatient case has not risen proportionately with cost per day, since the average length of stay has been reduced for most types of illness. The reduction applies particularly to surgical and obstetrical cases, and has been as much as 40 per cent in some institutions.

There has been a recent reduction in the demand for bed care among voluntary hospitals. This may be temporary, but the trend is noticeable in all parts of the country. Several factors have contributed to this condition; namely: the lowered birth rate, the practice of early ambulation, the increased use of diagnostic facilities by ambulant patients, and the lack of "ready cash" for elective surgery and hospitalization.

Many hospitals have diverted their attention from plans for expansion to a struggle for existence. It is not the first cost, but the upkeep, which causes most financial difficulties.

Every dollar invested in hospital facilities requires about 35 cents annually for expenses of operation. The depreciation on a $1,000,000 hospital's plant and building equipment is about $30,000 annually. But operating expenses for salaries and supplies are about $350,000 each year. The total annual costs of maintenance for a hospital are about 12 times the amount necessary as an allowance for replacement. Replacements or modernization of an existing hospital may, of course, effect a net saving to the community by permitting economies in current operation.

CURRENT PROBLEMS OF HOSPITAL FINANCE

The problems of hospital cost have their counterparts in the efforts to stabilize and achieve hospital income. There are three main sources of income available to voluntary hospitals, in differing proportions for each community and institution.

1. *Patient Fees*
   a. Group-payment subscribers
   b. Individual patients responsible for their own bills.
2. *Taxation*—This includes block-grants, as well as payments for services to cases "approved" by local, state, and federal government agencies.
3. *Philanthropy*, in the form of investment income, support by community chests and federations, and individual contributions.

Most voluntary hospitals have relied, to greater or less degree, upon taxation and philanthropy for a part of their current support. Public policy has required the hospitals to render service to patients in accord with their needs, and to look to the community for later reimbursement.

At the present time a great many hospitals report current expenses which exceed current income from all sources. The polite phrase for this result is "unreimbursed community service." The vernacular term is "deficit."

The net deficit of a specific hospital may be caused by one or more of the following: (a) a scale of charges for

service to individual patients which are below the amounts such patients are able and willing to pay; (b) demands by the community for services which involve costs beyond the amounts which the public pays for such services in taxes or philanthropy; (c) contractual arrangements with group-payment organizations for services at rates which are less than cost, or less than such subscribers as a group should reasonably be expected to pay for their care; (d) charity discounts to individual patients beyond the limits of public necessity and convenience, or beyond the amounts for which community reimbursement has been budgeted or guaranteed.

INCOME PROBLEMS

It is not always possible for a hospital to adjust its income to the expenditures incurred on behalf of patients. Charges to individual patients can be increased, and such rates, particularly for board and room service, are now much greater than in former years. Likewise, grants from government agencies can ultimately be increased, but usually with a time lag as far as costs are concerned, and nearly always with a reluctance on the part of the official agencies to meet the full costs of services to cases "approved" by their representatives. Even the enlightened Assembly of the Commonwealth of Pennsylvania, which appropriated $12,260,000 to 180 voluntary hospitals for the 1947–1949 biennium, has established a ceiling of $5.50 per day for reimbursement for the care of medical and surgical cases.

Most rigid of all types of hospital income are the various forms of voluntary philanthropy, namely: investment income, community chests and federations, and individual voluntary contributions. These amounts are not decreasing, but they finance a much smaller amount of hospital service than ever before. In the Philadelphia area, 10 years ago, they represented 30 per cent of the income of voluntary hospitals. Now the percentage is less than 15 per cent. The ratios are, of course, even lower in other parts of the country.

Good hospital care costs money which must be paid by someone. Up to the present time, voluntary hospitals have been able to survive half "pay" and half "free," as far as the patients are concerned. But behind the program of charitable service by the institution there has always been a struggle by the management and trustees to obtain current funds to pay salaries and purchase supplies for the hospital.

INCREASE OF CONTRACT PATIENTS

An outstanding feature of current finance is the reliance upon contractual income for relatively large groups of people and, accordingly, for large amounts of current revenue. The ability-to-pay principle in hospital charges has been gradually replaced by a "benefit" theory, according to which, individuals or groups are expected to pay their own way. This principle is sound, and it is proper that self-supporting people should also place hospital care in their family budgets along with other necessities.

The costs of hospital care have changed faster than the public's sense of responsibility for the financing of hospital service. A fund of $100,000 is now required to endow the annual maintenance cost of one occupied bed in an urban general hospital. Most voluntary hospitals do not have even this amount of endowment capital.

In the face of rising costs and broader utilization of hospital care by the community, fees charged to well-to-do patients cannot finance very much hospital service to other patients. Net revenue from patients is neither reliable nor adequate for financing charitable service in a hospital.

Private philanthropy finds that the same number of dollars will buy less service than formerly. Likewise, all patients find that the costs of food, clothes, and shelter have permitted a surprisingly small residue or savings for unpredictable hospital bills. Even with higher incomes, no individual can tell when he will need hospital care or what his sickness will cost him. And the standards of eligibility for free service, based on inability to pay for necessary care from private resources at the time of sickness, have been raised much above the levels thought socially justifiable a few years ago.

The problems vary in each voluntary hospital, but only in their detailed phases. Operating deficits are a common phenomenon, and they are not all traceable to unjustified expense. They tend to arise rather from a demand by the public for service in amounts and quantities beyond that for which they have been willing to pay.

PAYMENT OF COST ESSENTIAL

In the milieu of hospital financial problems which have just been described, it is important that group-payment plans assist in the solution of some of them rather than add new ones to those which already exist. Blue Cross subscribers, by definition, are self-supporting members of the community. They should pay their own way, and if they are concerned with free hospital service, it should be as contributors to, rather than recipients of, public charity and philanthropy.

A group-payment plan should pay the full costs of the services which are rendered to its subscribers during any period of time. In the long run, these payments should meet the costs of each hospital which contracts to provide service. If the costs of a specific hospital are so high as to outrage the public conscience, it should be reorganized administratively or excluded from full reimbursement in order to protect the interests of subscribers and well managed institutions.

Several factors make the application of the cost principle difficult to apply in practice. Such factors are the rapid or marked changes in the price level, differences in the type and complexity of the service provided by each hospital, changes in percentage of occupancy, and variations in the quality of management. Moreover, hospital costs may rise without regard to the adequacy of the subscription rates of group-payment plans, which rates can be adjusted only infrequently, and with the ultimate consent of the subscribers.

Upward changes in the costs of hospital care to subscribers of group-payment plans may be balanced by increased collections from subscribers, or by reduction of the hospital service furnished as a contract benefit. Many group-payment plans have felt that there is a maximum price which people will pay for hospital protection, beyond which price members of the public will decide to assume their risks individually. Accordingly, there has been a marked tendency to reduce the amount of protection rather than to increase the price.

DOLLAR-BENEFITS IN BLUE CROSS

The most common method of reducing protection has been the introduction of a co-insurance feature into the subscriber-contract, by which "dollar-benefits" are substituted for the assurance of certain forms of service. This feature has been applied particularly to board and room service. Board and room service has accounted for most of the recent increases in hospital costs, and has typically been "priced" relatively lower than the various special services. If dollar-benefits are to be substituted for service-benefits, the most defensible change is in the provision of board and room services which

are to some degree controllable by the patient as to type and duration.

Another widely adopted form of dollar-benefit is that applied to maternity admissions, an experience regarded by some actuaries as not an "insurable risk." Birth rates have always been higher among Blue Cross subscribers. People do not have babies *merely because* they join Blue Cross, but many do join Blue Cross *merely because* they expect to have babies. Strictly speaking, payments for maternity benefits might properly be charged to "public relations" expense, rather than included in the "loss-ratio" of a group payment plan.

The introduction of the co-insurance feature, or dollar-benefit, into group-payment plans has had several administrative advantages. It has permitted some group-payment plans to avoid a series of raises in subscription rates, which might have caused more cancellations than would have resulted from a reduction of benefits.

The dollar-benefit feature requires hospitals to collect additional sums from hospitalized subscribers in order to finance the service to such patients. The plan and the hospital have thus become " co-defendants " to the patients' " complaint " against rising hospital costs.

The dollar-benefit feature does not take the voluntary hospitals " out of the insurance business." They are still liable to provide their communities with certain types and amounts of service. The only question is whether it is better to collect the necessary funds (beyond existing dollar-benefits) directly from subscribers or through negotiation for a new rate of reimbursement from the group-payment plan.

Dollar-benefits are not the answer to the hospital's need for revenue or the public's desire for protection. A sick man needs service, not cash. Within his ability, he will pay the cash to assure the services he believes to be *necessary*.

FUTURE OF GROUP-PAYMENT

Health insurance is here to stay. The 32,000,000 Blue Cross subscribers and 19,000,000 commercial insurance policy holders are an impressive section of our public. These people are protected more or less adequately with various types of contracts. They all know that assurance of health service can be achieved through group action.

The primary concern of the public is how to obtain *necessary health "service."* This statement applies to the entire population, and particularly the participants in a group-payment plan for hospital or medical care. A group-payment plan that is well managed, and reasonably comprehensive and convenient, will grow in membership even though subscription rates are increased from time to time. If subscribers really like a plan (its benefits and management) they will pay whatever is necessary to keep it going. If subscribers do not like a plan, they will let it languish even at "cut prices." The essential problem thus becomes one of negotiation between the group-payment plan and the agencies which provide the service.

I have weighed and analyzed the data and arguments presented for and against the various forms of voluntary and compulsory health insurance. I have considered such problems as freedom of choice, quality of service, moral hazards, maintenance of standards, income limits, and eligibility for coverage. It is my opinion that all such considerations are secondary to the primary problem of how to contract for a certain type and quality of " service," and how to pay adequately and equitably for the contract benefits received.

From the standpoint of the hospitals, the most essential feature of a group-payment plan is assurance of enough money to enable them to produce the services they are expected to provide. Criticisms by hospitals of actual or

potential group-payment plans can nearly always be traced to the assertion or fear that insufficient funds are being, or will be, paid for the types and volume of service they are expected to give.

CONCLUSION

Group-payment plans should expect to pay the full costs of the services provided to their subscribers by hospitals. Expanding membership makes the payment of cost essential, since an increasing portion of hospital revenue is derived from this source. Payment of different amounts based upon different costs for nominally similar service is complicated, but can be achieved.

The general rise in costs creates a problem of obtaining sufficient money from subscribers to meet the costs of the hospital care provided. In my opinion, the payment of costs, even during changes in the price level, would be assisted by the following policies and procedures on the part of group-payment plans and voluntary hospitals.

1. *Provision of Comprehensive Service as the Contract Benefit* — The absence of dollar-benefits would focus the attention of the hospital and patient upon the service to be rendered rather than the fees to be paid for service at time of hospitalization. On the one hand, the subscriber would be more willing to pay an adequate subscription rate. On the other hand, the hospital would have an economic interest in providing only necessary care.

2. *Provision of "Basic" Rather than Semi-Private Board and Room Service* — This would not prevent assignment of patients to better accommodations when necessary to adequate care, or when voluntarily requested by subscribers after admission to the hospital. Much argument over "how much is enough" has arisen from the fact that contract accommodations contained a "luxury" element, and should be priced according to "ability to pay." Only basic service can be widely urged on the principle of public necessity and convenience.

Two types of dollar-benefit may, in the writer's opinion, be included in a non-profit group-payment program without doing violence to the principle of providing necessary service. One is a dollar-benefit for maternity cases; the other is substitution of suitable cash allowances for service benefits when a subscriber voluntarily elects to utilize other than "basic" room accommodations.

3. *Closer Coördination of Hospital and Medical Group-Payment Plans* — Voluntary hospitals and their attending staffs are professional partners, but economic competitors. Private medical or surgical fees to group-payment hospital patients have been the cause of considerable misunderstanding between doctor and patient. On the one hand, the physician may hesitate to give charity service to a Blue Cross subscriber, even though he cannot pay from his private resources. On the other hand, a Blue Cross subscriber may feel that, with hospital coverage only, he has less protection than he would have enjoyed as a "charity case." The future of private medicine and voluntary hospitals is interdependent. The total expense of hospitalized illness must be budgeted as a single item if voluntary prepayment is to be satisfactory to patients, doctors, and hospitals.

4. *Subscription Rates Must Be Payable on Terms That Permit the Widest Possible Participation* — Comprehensive hospital and medical protection requires a contribution by the employer if low-income workers are to enroll in large numbers. The contribution by the employer may be a proportion of the subscription rate, or a supplemental payment above a uniform deduction for each employee.

It is immaterial whether the total subscription is ultimately paid by the

customer, the stockholder, or the wage-earner. The important fact is that payments by the workers be considered reasonable by them. The practice of employer contribution is, of course, generally required by commercial insurance companies offering group life and health benefits. An increasing number consider the contributions as a form of additional wage or prerequisite for all employees.

Hospitals collect money in order to provide service. They do not provide service in order to collect money. But money and service are inseparable. Neither a group-payment plan nor a hospital can long continue to expend more money than it receives, even for a good cause.

The basic problem caused by rising costs is simply how to raise and disburse enough money to meet those costs. Dollar allowances are merely a stopgap. They are basically an admission that the public does not care enough for hospital protection to pay the price, or that they wistfully hope the bill will be paid from some other source. Group-payment is the best way to raise the money. If group-payment plans are to survive under voluntary auspices, they must pay the voluntary hospitals what it costs to service the group-payment subscribers.

Lectures to the Laity—New York Academy of Medicine

The Fourteenth Series of Lectures to the Laity of the New York Academy of Medicine, 2 East 103rd Street, New York City, began November 17 with the Linsly R. Williams Memorial Lecture by Robert P. Patterson, former Secretary of War, on "Some Problems in Law and Medicine." The second number was on the subject "The Endocrines: Masters or Servants?" by Ephraim Shorr, M.D., of the Department of Medicine, Cornell University Medical College, New York. The third address was "Science under Dictatorship," by Leo Alexander, M.D., Director, Neurobiologic Unit Division of Psychiatric Research, Boston State Hospital.

Other lectures will be held on January 13, January 27, and February 10, all at 8:30 P.M. The first of these will be on "Blood and Man," by William C. Boyd, Ph.D., of Department of Biochemistry, Boston University School of Medicine. John Ray Dunning, Ph.D., Professor of Physics, Columbia University, New York, will speak on "The Future of Nuclear Energy," and finally George B. Gardner, M.D., Executive Director of the Judge Baker Guidance Center, Boston, will speak on "The Criminal in Our Midst." Admission is free and the public is invited to attend. The lectures are broadcast by WNYC and WNYC-FM.

The "Yes" and "No" of Nutrition and Natural Resistance to Infectious Disease*

HOWARD A. SCHNEIDER, PH.D.

Associate in Physiology, The Rockefeller Institute for Medical Research, New York, N. Y.

IT is my estimate that this audience expects, and is entitled to, a straightforward answer to the question, "Can the food we eat affect our resistance to infectious disease?" In our laboratory we have been facing this question for the past eight years. Now, in fifteen minutes, I must give you my reply. It is a challenging assignment, and since, in Boston, we are not far from Walden Pond, it is perhaps fitting that we recall the challenge of Thoreau, "Simplify! Simplify!" Simplify we shall have to, but what answer will we give to the question, "Can the food we eat affect our resistance to infectious disease?" My answer is, "Sometimes yes, sometimes no." In the rest of the time allotted to me I shall have to show you (1) that my answer is "straightforward" and not a kind of scientific pussyfooting, and (2) how I believe our knowledge of this controversial subject can be extended so that the answer can be made to approach the unequivocal.

To begin with, the question, as I have put it, admits initially that there is such a phenomenon as natural resistance to infectious disease, a term we may define as an abbreviated description of the direct observation that a pathogenic microbe, be it bacterium, virus or fungus, does not always produce the signs and symptoms of infectious disease when presented to a prospective host even though that presentation may be the very first for that particular host. Such hosts we designate as "naturally resistant." When next we come to inquire as to the basis for this natural resistance we are first presented with the biological fact that such natural differences in susceptibility to infectious disease are capable of being categorized by the same biological groupings we designate as species. Thus man, as a species, is susceptible to measles, but mice are not, or, as we say, mice are "naturally resistant." Why this is so we have no very good way of knowing, although we suspect that the real reason is connected somehow with the genetic basis for the difference between mice and men. This *interspecific* difference is such a great one, on any plane one may want to consider it, that I think you will not accuse me of being fainthearted if I suggest it is too much to expect that diet can alter these facts. So that in these instances of inter-specific differences in susceptibility to infectious disease we must say, "No" to the question of the influence of diet.

It is sometimes observed, however, that *within* a species, great differences in susceptibility may exist among populations when a microbic species, which experience has shown generally to be pathogenic for the given host species,

* Presented at a Joint Session of the Food and Nutrition and Laboratory Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 11, 1948.

is presented in the identical way to representative samples of the host. This is, of course, the familiar fact of variation of a biological character, in this instance, susceptibility to a given pathogen. Now, again, variation may be due to either (1) genetic or (2) environmental causes. Diet is an environmental agent and now the trail begins to grow warm. In the case of these *intra-specific* differences in natural resistance does diet exert any influence? The answer— "Sometimes yes, sometimes no!" I answer in this wise, not because I approve of being pusillanimous while on a public platform, but because of the hard facts of the natural world. The fact is that even environmental agents, such as diet, must produce their effects in the physiology of the host and this physiology is operating within a genetic framework. In natural populations of hosts this framework is sometimes plastic to the effect of environment, and thus an environmental agent makes its effect evident, or the genetic framework is rigid and the environmental effect is not possible, the given character being innately determined in its appearance or non-appearance. Our scientific interest is now focused on describing those genetic conditions in which the genetic framework, or genotype, is plastic to the effect of diet. In the instance of mice, and an infectious disease of mice, Salmonellosis, I believe we are now in possession of information, obtained in our own laboratory,[1-3] which will permit us to offer such a description. Without further ado let us examine experimentally the various genetic circumstances in which host and pathogen can meet, and see for ourselves when diet has an effect on natural resistance and when it does not, when we can say "Yes" and when we must say "No."

Before we do this I shall beg your permission to abbreviate my remarks somewhat. From what has preceded I think it is obvious that in any examination of our problem we must take into account the genetic factors, *both in host and pathogen.* Thus far we had not mentioned the variation existent among pathogenic species, but there is certainly no novelty in the fact that virulent and avirulent representatives are recognized to exist, and a third possibility is, of course, a pathogen population consisting of a mixture of these two. Among hosts we can recognize three great classes also: (1) Inbred, genetically uniform, resistant stocks, (2) similar susceptible stocks, and (3) outbred, genetically heterogeneous stocks. Now when these three classes of hosts meet with these three classses of a pathogen species, we can examine the effect of diet. That will make nine instances which we will test. But what diets will we test? For reasons which here must be passed over let us test the effect of a diet of natural foodstuffs, whole wheat and milk, and compare that with a synthetic diet containing all of the essentials known for mice. The results are presented in Figure 1.

In eight out of the nine instances set forth there was no dietary effect observable in terms of differences in survivorship following infection. But in one instance there was such an effect. And so, when the question was put in nine different circumstances, eight times the answer was "No," and only once was it "Yes." On the face of it this is a poor showing for those who would claim that nutrition *does* influence natural resistance, but let us examine more closely the circumstances of the single "Yes." In this instance hosts which were genetically heterogeneous were infected by mixed populations of virulent and avirulent pathogenic bacteria. But in the natural world this is what probably is going on all the time. Certainly man is genetically heterogeneous and it is very probable that the pathogen populations he encounters are not pure

The Effect of a Natural (N) and a Synthetic (S) Diet on Survivorship following Infection in Nine Different Genetic Circumstances

		Host-Genotype		
		Inbred, selected, resistant	Random-bred, (outbred) non-selected	Inbred, selected, susceptible
Pathogen-Genotype	Uniformly virulent	N-Died S-Died	N-Died S-Died	N-Died S-Died
	Mixed virulent and avirulent	N-Survived S-Survived	N-Survived ↑ Dietary effect ↓ S - Died	N-Died S-Died
	Uniformly avirulent	N-Survived S-Survived	N-Survived S-Survived	N-Survived S-Survived

FIGURE 1

cultures, but mixed. So the single "Yes" is more important than it appeared at first sight, for it represents the vast bulk of the experience of the natural world. It is the abstractions of the laboratory which have provided us with several replies of "No." These negative answers are not false or wrong, rather we must say that in the natural world their probability of occurrence is a small one. We might say, then, that in the natural world the answer to our question, "Can diet influence natural resistance?" is a little "No" and a bigger "Yes."

Returning to our own specific disease model, in terms of mice and mouse typhoid, we can now say that the dietary agent responsible for increased survivorship is in the whole wheat, and, by experiment, has been localized in the germ. It is probably a new nutritional entity since it is not replaceable in its effects by any of the nutrients thus far

recognized, including all of the known vitamins. We are now engaged in the task of isolating and identifying this compound. When we have it in our hands we will, I am sure, by increasing the level at which it exists in the dietary environment, diminish the "No" and increase the "Yes."

"Protect the Family . . . Stamp Out VD" 1949 Social Hygiene Day Theme

Aimed at eradicating the nation's No. 1 communicable disease problem, the venereal diseases, the nation-wide observance of National Social Hygiene Day has been scheduled for February 2, 1949, according to Dr. Walter Clarke, Executive Director of the American Social Hygiene Association.

The theme of this year's observance is "Protect the Family . . . Stamp Out VD." "More than ever today it is recognized that the fight against venereal disease is the fight for the strongest family life for our country," Dr. Clarke pointed out. "Syphilis and gonorrhea are two of the greatest enemies of marriage and parenthood," he said. "The fight against VD is a fight for the children of our country—children who have a right to grow up as whole human beings—whole in body, mind, and spirit with insight into the true place of sex in life.

"This year the American Social Hygiene Association is faced with a new challenge with the national emphasis on defense activities. The nation's Armed Forces recognize the protection of American family life as the chief reason and best way of preventing venereal diseases among military personnel."

The American Social Hygiene Association has been requested by the U. S. Interdepartmental Committee on Venereal Disease to aid in the problem of venereal disease control as well as in the encouragement of the establishment of wholesome recreational and other activities in all local communities.

Social Hygiene Day will be observed in many cities at meetings, rallies, institutes, and forums on February 2, and throughout the rest of the month.

Program and publicity aid materials may be secured by writing to the American Social Hygiene Association, 1790 Broadway, New York 19, N. Y.

A Community Program for the Control of Rheumatic Fever

GEORGE C. GRIFFITH, M.D., F.A.C.P.

Clinical Professor of Medicine, University of Southern California; Chief, Cardiac Clinic, Los Angeles County Hospital, Los Angeles, Calif.

THE purpose of this paper is threefold: (1) to point out the importance of the problem, (2) to suggest a plan for community action in the control of rheumatic fever, (3) to urge physicians to initiate such community organization.

As a result of the work of Paul,[1] Swift,[2] Hedley,[3] Jones,[4] Wilson,[5] Sampson,[6] and many others, physicians are gradually becoming aware of the disease and its public health aspects. The public health aspects have been reviewed recently by Griffith,[7] pointing out that rheumatic fever, together with tuberculosis and syphilis, constitute the remaining big three infectious problems in American communities.

IMPORTANCE OF THE PROBLEM

Rheumatic fever, an acute, systemic, post-streptococcal, hypersensitivity syndrome with protean manifestations, is important, not only because of the morbidity and mortality, but because of its cardiac pathology, necessitating a public health program to include case finding, proper diagnosis, and provision for adequate long-time care.

Mortality statistics, in spite of under reporting, show a combined rheumatic fever rate for all ages of 20 per 100,000 in 1942.[8] From age 5 to 19, it is, among diseases, the leading cause of death.[9] Mortality statistics do not tell the whole story, for it is this infection which incapacitates and limits the earning power of many thousands during the prime of life. Furthermore, such handicapped individuals become nervously ill, frustrated and unhappy in their limited way of life. The size of such a group of individuals is shown by the medical examination of draftees, approximately 40 per 1,000.[10] Of the first 1,000 selectees rejected because of cardiovascular problems which the author assisted in reëvaluating in the City of Philadelphia, 69 per cent had either rheumatic fever or rheumatic heart disease.[11] In various cities throughout the United States, the incidence of rheumatic heart disease is shown by the following studies: in Cincinnati, 2 per 1,000[12]; in Philadelphia, 3.9 per 1,000[13]; in New York City, 8.8 per 1,000[14]; and in San Francisco, 2.2 per 1,000. In 1945 Sampson[15] reported studies of three different communities in California revealing an average incidence of 1.6 per cent.

The author, utilizing methods to be described later in this paper, found an incidence of 2.7 per cent in the school districts of Ontario and Upland, Calif., out of 2,769 children examined; while in Pasadena, a similar study of 2,159 children showed an incidence of 2.6 per cent.

The Los Angeles Heart Association sent out a questionnaire to 7,200 physicians on August 20, 1948, requesting information regarding the number of rheumatic fever cases, rheumatic fever suspects, rheumatic heart cases, and the

TABLE 1

Questionnaire on Rheumatic Fever, Rheumatic Heart Disease and Congenital Heart Disease

	Number of Patients			*Number Needing Institutional Care*		
	Total	*20 and Under*	*21–35*	*Total*	*20 and Under*	*21–35*
Rheumatic Fever	469	337	132	109	71	38
Suspected Rheumatic Fever	394	304	90	30	20	10
Rheumatic Heart Disease	1,726	607	1,119	238	73	165
Congenital Heart Disease	554	369	185	30	16	14
Total	3,143	1,617	1,526	407	180	227

number of congenital heart cases under private care; 23.9 per cent of the physicians returned the questionnaire in time for tabulation by September 7, 1948.

This response, although incomplete, shows the number of rheumatic fever patients in this county, and that 407 of them should be treated in an institution giving complete care.

In the past 9 months, on the Los Angeles County Hospital In-Patient Services alone, 234 patients with rheumatic fever under the age of 21 have been discharged, most of whom should be in a good convalescent hospital. Clearly, these facts show the need for organized efforts to control the disease.

ETIOLOGICAL FACTORS

Since World War I it has been generally known that rheumatic fever tends to occur in epidemics and to follow epidemics of streptococcal sore throat and scarlet fever. The best and most recent examples of this truth are the statistics obtained on my recent visit to the Far East Command. Statistics for 1947 were obtained from Colonel A. H. Thompson from the 8th Army Area in Japan, and from Colonel C. P. Ward from the 24th Corps Area in Korea.

The cases of rheumatic fever followed the streptococcal infections by 2 to 6 weeks. The very high percentage of rheumatic fever is unexplained. The usual percentage of post-streptococcal nonsuppurative complications in the United States is about 5 per cent.

Socio-economic factors appear to influence the occurrence rate of rheumatic fever as pointed out by Paul.[3] The disease also tends to be concentrated in families.[15] This thought must be correlated with the studies of the author showing that the home is a point of contact, and that a boy from a rheumatic home is not more likely to develop rheumatic fever after he leaves home than a boy from a non-rheumatic home.[16] All these facts, including psychological ones, should be utilized in an organized effort to control rheumatic fever.

TABLE 2

Relationship of Known Streptococcal Sore Throats and Scarlet Fever to Rheumatic Fever in Far East Command for 1947

	Total Number Cases of		*Total Number Cases of Rheumatic Fever*	*Per cent*
	Strept. Sore Throat	*Scarlet Fever*		
Korea	372	182	209	36.0
Japan	834	2,036	835	29.0

COÖPERATION A NECESSITY

To make proper use of the knowledge we already possess, requires the mobilization and organization of all community resources. Rheumatic fever cannot be controlled by the physician alone. The physician finds the socio-economic, the psychological, and the epidemiological aspects of the disease beyond his ability, and requires community coöperation. To this end, education of parents, teachers, social workers, school nurses, and, above all else, physicians, is necessary to detect the early manifestations of the disease, to practise the best child health care, to seek diagnostic serv-

ices, and to provide convalescent care with educational and occupational services.

ORGANIZED ACTION

There are promising signs of local action. In many cities such as Los Angeles, educational programs are given at regular intervals. Many states now require that the disease be reported, and in some large cities cardiac diagnostic services have been made available.

From the federal level, the Children's Bureau has been assisting state agencies since 1939. In 1944, the American Heart Association called a conference of medical, governmental, and social organizations, and adopted resolutions to (1) seek aid from public and private funds in order to increase the basic knowledge of the disease for professional education and for increasing public awareness, (2) to form a Council on Rheumatic Fever. This council was formed, and after consideration, felt that the greatest present need is to assist physicians and others to develop an overall community program for the control of rheumatic fever.

WHAT SHOULD BE DONE?

The pattern for rheumatic fever control should follow that utilized to control tuberculosis. The Framingham Tuberculosis Demonstration[17] set the pattern for an adequate community control. The following objectives were set up.

1. The magnitude of the problem must be known.
2. Expert consultation service must be provided for the practising physician.
3. Standards for diagnosis must be determined.
4. Economic and environmental studies should be evaluated.
5. Health education must be directed toward personal hygienic living and toward building of body resistance.
6. Provision for adequate treatment outside of the home for all economic levels should be made.

A LOCAL PROGRAM

Rutstein,[18] in a recent issue of the *American Journal of Public Health*, reported on and summarized the findings of a symposium on a community program for rheumatic fever. Many local control programs have been initiated. The most successful is the one at Stamford, Conn.

Summarizing the reported experiences of others and the writer's own experience in rheumatic fever, the following objectives were set up prior to instituting a rheumatic fever control program in a local California community.

1. Enlist the active coöperation of organized medicine.
2. Enlist the interest and aid of the local school officials, the public health officers, public health nurses, school physicians, school nurses, the local hospital administration, and civic groups as the P.T.A. and Junior League.
3. Establish a method for case finding.
4. Diagnostic Rheumatic Fever Clinic must be available without charge to all.
5. Follow up service organized.
6. Social service objectives determined.
7. Institutional care provided.
8. Educational and occupational guidance facilities must be made available.

The locality selected for this community rheumatic fever control program comprised the Ontario and Upland municipalities located in the Western end of San Bernardino County, California. This community is situated 50 miles inland from the sea coast, and is in the heart of the citrus and grape industries. The community became extremely rheumatic fever conscious because of the constant contact with patients from the Rheumatic Fever Unit of the Corona Naval Hospital. During the war, hundreds of patients from this unit were entertained and aided in many ways by the citizens of the area.

COÖPERATION OBTAINED

The administrator of the local hospital, Dr. A. A. Aita, and the president of the hospital clinical staff held dinner meetings at which the hospital medical

staff discussed the problem of rheumatic fever. The hospital and the staff agreed to give every aid in setting up the program. In this locality, all reputable physicians are members of the hospital staff.

CASE FINDING

The local school authorities, the school physicians, the school nurses, public health officials, and public health nurses gave full coöperation in case finding, examining every child in the schools, at ages 6 to 12 inclusive.

DIAGNOSTIC CLINIC ORGANIZED

The hospital administration provided space, consisting of a large waiting room, three examining tables, desks, chairs, gowns, and linen. A hospital technician, Flora Marvin, made appointments and managed the physical details of the clinic. The school nurses and public health nurses under the direction of Bertha Schwarzwelder, R.N., attended the clinic, one nurse assisting each examining physician. A careful history, complete physical examination, full blood count, urinalysis and sedimentation rate, electrocardiogram and fluoroscopic study were done on the first visit. For each patient admitted to the clinic, a record folder containing the above information was provided. The chief of the clinic consulted with each of the attending clinicians, namely, Drs. E. O. Carlson, G. S. Coltain, and R. N. Williams, and after careful discussion by the group, arrived at a diagnosis based upon the criteria set up by Jones [19] and Griffith.[20] Immediately upon the conclusion of the clinic, a letter was dictated to the hospital secretary, Audrey Richings, and typed in triplicate, the original copy going to the family physician or the public health physician, or the school physician; the second copy was filed in the record folder; and the third copy filed with the hospital's permanent records. The letter contained complete history, physical examination, record of laboratory results, diagnosis, recommendations for treatment, and an appointment for follow-up in 3 to 6 months' time if the patient was under the care of a private physician, or a return appointment in 2 to 4 weeks if the parents could not afford a private physician.

ADMITTANCE

All patients were admitted and studied without social service investigation of ability to pay. The patients from private physicians paid for laboratory work only if the physician so advised.

The attending physicians, the nurses, technicians, and secretary made no charge for their services.

The cost of the entire clinic per patient was $16 per case studied. The expense was met by the Community Hospital through its administrator and the Board of Trustees. The local Junior League provided funds for the second year of the clinic.

FOLLOW UP

The physicians returned their private patients for follow up consultations regularly.

The public health nurses visited the homes of both private cases and those with substandard incomes. Parents were interviewed by the physicians in the clinic and instruction was given. The public health nurses helped the parents to carry out such directions where no private physician was in attendance.

Careful attention was given to the early detection of upper respiratory infections and for possible recrudescence of rheumatic activity by the physicians and visiting nurses.

At the present time, a survey for possible streptococcal carriers is in operation. A culture is taken from all throats in the home where the patient resides.

Convalescent care in a rheumatic fever hospital was possible in only one

A. EVELYN

case. It is believed that many of the patients, from the better as well as the poorer homes, would do better in a convalescent heart hospital. This method of treatment prevents to a large degree epidemic streptococcal throat infections and provides a routine of rest and adequate food. The psychological needs of the child are met better in the convalescent home. Educational facilities are provided by well integrated teachers, and occupational guidance as well as supervised play, aid greatly in the maintenance of a rounded development for the rheumatic child.

As a result of the community program at Ontario and Upland, 3,840 children were observed, with an incidence of the rheumatic state during 1946 of 2.74 per cent, and in 1947 of 2.2 per cent.

Tuberculosis Nursing Course

The Department of Public Health Nursing, College of Medicine, Syracuse University, in coöperation with the New York City Department of Hospitals and the New York State Department of Health, will offer a course in tuberculosis nursing during the spring semester, 1949. The course is being offered for public health nursing supervisors and senior nurses, and those preparing for consultant positions. Field experience in tuberculosis community nursing will be given in Syracuse and clinical experience at Triboro Hospital, New York.

The semester runs from February 4 to May 31, with registration from January 31 to February 3. Apply to Margaret Shetland, Acting Director, Department of Public Health Nursing, Syracuse University, Syracuse, N. Y.

A Program of Inservice Training for the Health Department Staff*

ANN WILSON HAYNES, F.A.P.H.A.

Chief, Bureau of Health Education, California State Department of Public Health, San Francisco, Calif.

EXPERIENCE of the California State Department of Public Health has demonstrated that a real contribution to the improvement of a departmental program and its efficiency can be made by planned, continuous inservice training which meets the needs of the staff.

The California inservice program was started in January, 1947, on the recommendation of three staff committees which, over a period of more than a year, studied the problem and experimented with various phases of inservice training. Among the staff needs which were recognized by the committees were the following:

1. The orientation of new employees
2. Better understanding by all employees of departmental problems, planning, policies, and programs
3. Opportunity for a larger number of the staff to participate in planning, in solving problems, and in formulating policies
4. Help to all the members of the staff in acquiring a respect for the value of their own and other people's work and an understanding of the work problems of other people
5. Help to all the staff in acquiring a feeling of belongingness
6. Opportunity for all the staff to grow on the job
7. Involvement of the staff in the development of the inservice program

Certain difficulties stood in the way of the development of a complete inservice program. California is the second largest state in the Union. Although headquarters offices are in the San Francisco Bay area, a staff of approximately 800 persons is housed in 12 different buildings in four cities, or is working out of these offices in the field. The departmental program is broad and is expanding. Job classifications utilized by the department in the employment of staff range from unskilled workers to highly trained scientists and administrators. A fast tempo of work is maintained throughout the department, a factor which, at the start of the program, caused some administrators to question whether time could be spared for inservice training.

An analysis of the difficulties which have been mentioned revealed that it was impractical to start with a program that would meet completely all the needs which had been recognized. A pragmatic view was adopted and it was decided to start somewhere short of the ideal with a program which would meet some of the more urgent needs and which was sufficiently flexible to provide for growth and for change as other needs were recognized.

THE PRESENT PROGRAM

Although the Bureau of Health Education has administrative responsibility for inservice training, the program itself is conducted by the entire department, with broad staff participation in all of its phases. The program which has

* Presented before the Public Health Education Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

operated continuously with minor changes for nearly two years may be divided into four parts: orientation of new employees; general staff meetings; a house organ; and special educational opportunities for the staff.

1. *Orientation of New Employees*—Within a month after employment, new employees in key positions such as those in professional, administrative, technical, and senior clerical classifications spend 4 days in one hour visits to the San Francisco Bay area offices of each bureau and of the two Divisions, Laboratories and Local Health Services, which conduct operating programs. (The other three Divisions, Administration, Environmental Sanitation, and Preventive Medical Services, do not conduct operating programs but coördinate the work of bureaus.) Although the department maintains offices in four cities, headquarters of all divisions and bureaus are in the Bay area in either San Francisco or Berkeley.

The group of new employees is kept under 10, so that there may be opportunity for questions and informal discussion. Although a one hour visit does not permit the acquisition of very extensive knowledge, it is long enough for new staff members to get some understanding of program and problems, to become acquainted with some of the key members of the department staff, to see the physical plant and to observe some of the programs in action, as in the laboratories and in the offices where machine tabulation of data is done.

The orientation program for employees in key positions is regularly scheduled for the first 4 days of the last week of each month. Division and bureau chiefs have been requested by the director not to delegate responsibility for meeting with the group of new employees.

After the group of new employees in key positions has completed 4 days in this special orientation program, they meet with all other new employees for a half-day session on Friday morning with the director and the five division chiefs. This larger group usually numbers about 20 and includes all new employees. Discussion at this meeting centers around the overall program of the department and so serves the dual purpose of tying together the information which has been acquired by the special group in the 4 day program and of giving some orientation to new staff members who attend only this one session.

When the orientation program had been in operation for a year, we had on hand a backlog of more than 70 requests for inclusion in the program from employees who had been with the department for some time—in one case for 30 years. Arrangements were made to schedule two groups, both of which included new and old employees, for each month during the first 6 months of 1948. Division and Bureau chiefs willingly accepted the responsibility of devoting 2 hours instead of 1 each month to meeting with new employees.

Staff members of the State Department of Finance and the State Personnel Board have taken the orientation course. At the present time plans are under way to invite key staff of local health departments to participate in the program. The possibility of utilizing the program to orient the staffs of other state agencies and of local health departments was not originally contemplated. Without a planned, continuous inservice program it would not be possible to give this important educational service to other agencies.

2. *General Staff Meetings*—Although meetings of the administrative staff have been the custom in the department for some years, regularly scheduled, planned meetings for all the staff were not held before the inauguration of the present inservice program. The plan which has been followed since the start of the pro-

gram is to hold a 1½ hour general staff meeting on Friday of the week in each month, which is devoted to inservice training. Tea is served at the close of the meeting.

Programs for the current year are being selected on the basis of desires expressed by staff through a questionnaire which was distributed with pay checks in January; however, there is flexibility to meet situations which could not be anticipated and to give the staff an opportunity to hear visiting celebrities. There is a conscious effort to provide variety in topics and in methods of presentation. For example, these are typical programs: a panel discussion of legislative plans by the director and division chiefs; a presentation of research in encephalitis control by staff members participating in the research; group discussion of departmental policies relating to local health departments led by a representative of the American Public Health Association; the showing of new films and group discussion of them led by staff of the Bureau of Health Education; a presentation of state civil service policies and practices by the staff of the State Personnel Board.

Participants are asked to make clear presentations which can be understood by any intelligent person who is not an expert in the specific field covered but are warned not to "talk down" to the group. Frequently, technical material is presented. Nevertheless, the meetings continue to be attended by about an equal proportion of professional and clerical staff, apparently with equal enjoyment by both groups.

3. *House Organ*—Each member of the staff receives a copy of a house organ entitled "Just Between Us" which is issued in mimeographed form once a month.

Although the Bureau of Health Education has editorial responsibility, much of the material in "Just Between Us" is written and contributed by staff members throughout the department. A typical issue includes a message from the director, an article on personal hygiene, news of activities of the staff such as vacation plans, marriages, and births, a welcome to new staff members, a description of one phase of the departmental program or a personality sketch of a staff member. There is a sprinkling of cartoons, jokes, and rhymes. The style is informal, newsy, and friendly.

4. *Special Educational Opportunities*—Each bureau and division of the department provides, in varying degrees, planned programs of inservice education for its staff. The Personnel Office arranges refresher courses for the clerical staff. In addition, there has been recognized a need to provide opportunities for inservice education which are not limited to staff in any one division, bureau, or job classification. A beginning was made in arranging last spring a special course in California Government which was taught by a member of the faculty of the State University. Persons who enrolled were from professional, technical, and clerical fields, and ranged in job classification from bureau chief to senior stenographer. A departmental committee is now assisting the Bureau of Health Education in ascertaining staff needs for similar programs and in developing a plan to meet these needs.

EVALUATION

No formal attempt has been made to evaluate the inservice program. Its limitations are recognized and some of them have been mentioned.

There has been tangible evidence that the program has staff approval. The requests by staff members who had been with the department for a period of years to participate in the orientation program indicate that this service is helpful. These requests were often accompanied by a statement such as,

"The newest employee in our office knows more about the department than I." Comments of new employees have been collected. The one which pleased us most was made by a stenographer who, in describing the orientation program to a friend, said, "It's a wonderful place to work. You know, they really care about you." A good attendance has been maintained at the general staff meetings which have shown improvement both in methods of presentation and in audience participation. From comments of staff and from staff contributions of editorial material, it is known that "Just Between Us" is widely read and appreciated. There was a capacity enrollment in the one special course that was offered and we have had requests for additional courses.

Administrators report better staff morale and less staff turnover. Concern with these two problems was an important motivation in starting the inservice program. It is believed that the inservice program, by meeting, at least partially, the staff needs which have been mentioned, has contributed to this improvement.

During the period of our experience with inservice training there has been observable improvement in departmental administrative policies and operation. It is not possible to measure the contribution of the inservice program, and certainly other factors are involved. Experience in planning and operation of the inservice program has helped administrators recognize staff needs and find ways of meeting them. In a number of divisions and bureaus there has been improvement of personnel practices including planned orientation of new employees within the division or bureau, regularly scheduled staff meetings, committee work, and social activities. The department has established a canteen for employees in San Francisco, a simple thing in itself but an action that has done much to promote staff friendships and give employees a feeling of belongingness. There is a movement coming from both administrators and rank and file employees to form an employees' association. Most important has been the provision by administrators of increased opportunity for the staff to participate in planning, in solving problems, and in formulating policies.

The changes in administrative policies which have been mentioned would perhaps have evolved in any case; it is believed, however, that the experience of administrators in thinking through staff needs and in planning and participating in the inservice program has hastened the process of evolution.

Popular Magazine Discovers Local Health Units

Collier's Weekly for January 22 will have an article discussing the need for at least basic minimum local health services to cover the entire nation. Its dramatic title is "The Shame of Our Local Health Departments."

Public Health Degrees and Certificates Granted in the United States and Canada during the Academic Year, 1947-1948

The Committee on Professional Education for the 15th consecutive year presents its annual report of Public Health Degrees and Certificates Granted. Because of the special concern which the Engineering Project has had in recruitment and training of engineers for public health services, the material on students and degrees in sanitary or public health engineering is more complete for the academic year 1947–1948, than it has been in earlier years. This should be borne in mind in studying the figures.

In addition, the current report includes the findings of a special study made of undergraduate students and degrees in sanitary engineering.

As has been the practice for the past two years, summary tables only are included in this report. More detailed tabulations such as have been prepared in previous years are available in mimeograph form on request from the office of the Association. In the 5 year tables, certain minor corrections have been made in figures for 1946–1947, following further clarification by administrative officers of some of the schools.

The present report, as formerly, is based on questionnaires submitted by the administrative officers of the schools training graduate students. Their replies have been subjected to statistical review only. The tabulations are shown for graduate students in public health, public health or sanitary engineering, and public health nursing. The first two groups include only Master's degrees, or their equivalent, or higher academic degrees; the last mentioned includes students receiving Baccalaureate degrees or certificates, or equivalent, in public health nursing. The National Organization for Public Health Nursing has prepared the material on public health nursing students and degrees and given permission to include the data as a part of this report.

The report is based on replies received from three groups of schools; those 16 giving public health degrees, including the 10 schools of public health accredited through the A.P.H.A. accreditation program; from 41 universities offering graduate degrees in public health engineering or sanitary engineering; and, finally, from schools with 37 approved programs of study in public health nursing or approved basic curricula. A number of schools, it will be understood, are in more than one category, that is, some of the universities gave public health degrees, public health engineering degrees, and nursing degrees or certificates.

ENROLLMENT TRENDS

The figures for the current year indicate a slowing up of the increases that have appeared in previous post-war years. The total number enrolled in public health courses increased slightly. Engineering student enrollments as reported also show an increase of more than 10 per cent, but this increase is due almost entirely to the larger number of schools reporting.

As to degrees granted, there has been a slight drop in public health degrees and an increase of about one-fifth in public health engineering degrees after

making allowance for additional schools reporting. Degrees and certificates for graduate nurses were reported from all approved programs of study for the first time in recent years. After allowing for schools previously unreported there has been an increase of about one-sixth in the number of graduate degrees and certificates granted through approved programs over the previous year.

The proportion of physicians among those enrolled in public health courses has been about 40 per cent of the total enrollment during the current year and the two years previous, in absolute numbers 244, 298, and 302 in these years. For the eight years during which information on professional background of students in graduate public health courses has been secured, nearly 1,900 physicians have been enrolled representing 42 per cent of total enrollment. In the first two of those years physicians made up more than half of the graduate students; in the academic year 1943–1944 they were only one-third. Health educators represent the next largest group, less than 20 per cent in 1947–1948, a substantial reduction from the 29 per cent of the total two years ago. Laboratory workers have increased from 33 in 1944–1945 to 89 in 1947–1948, from 7 to 12 per cent of the total enrollment.

With the expanding concept of public health, a new group has come into public health schools in the last two years in appreciable numbers. The number of hospital administrators, enrolled almost exclusively in the special courses given at Columbia University and the University of Minnesota, numbered 49 last year and 94 in the current academic year, in which they constitute nearly 13 per cent of the total enrollment in graduate public health courses.

NUMBER OF DEGREES GRANTED

With the exception of Toronto University and the University of Puerto Rico, where different traditions of nomenclature prevail, the number of separate degrees offered for public health students has now been reduced to 8, including Master of Hospital Administration. The most common degrees offered are Master of Public Health by 10 schools, and Doctor of Public Health by 7.

There has been less consolidation of degrees in public health engineering or sanitary engineering. Originally the 41 schools reported a total of 25 different degrees. In analyzing the material it has been assumed, however, that the distinction between Master of Science, Sanitary Engineering; and Master of Science in Sanitary Engineering is a distinction without a difference. The same assumption has been made for Master of Science, Civil Engineering, and Master of Science in Civil Engineering; and for Master of Science, Civil Engineering (Sanitary Option), and Master of Science, Civil Engineering, (Sanitary Engineering Option). Other probably reasonable consolidations have

TABLE 1—ENROLLMENT IN GRADUATE PUBLIC HEALTH COURSES AND STUDENTS RECEIVING GRADUATE DEGREES OR CERTIFICATES, FIVE YEAR SUMMARY, 1944–1948

[a] Includes a number of new degrees not hitherto reported—Master of Science, Engineering 19, Master of Hospital Administration 11, Master of Health Education 8

not been made in the current tabulations in the hope that the display of minute variations may hasten the process of reducing the nomenclature of public health engineering degrees to a common denominator.

Of the 528 students receiving graduate public health degrees, almost 70 per cent received the M.P.H. degree, or its Canadian equivalent, Diploma in Public Health; 44 persons, largely those in Columbia University's Hospital Administration course, received the M.S. degree; 20 persons, the Certificate of Medical Technology granted by the University of Puerto Rico; no other degree was granted to as many as 20 persons.

Among the sanitary engineering group of 179, only 3 degrees were given to more than 20 persons; M.S., or its Canadian equivalent M.A.Sc., to 57; M.S.S.E. (or M.S. in S.E.) to 34; and M.P.H. to 34. The remaining 54 persons received 12 different degrees.

Among the 1,701 students receiving public health nursing degrees, 126—about 7 per cent—received the Master's degree, a considerable drop in the proportion of these degrees over the previous year. Those receiving certificates also dropped from 42 to 33 per cent of the total. Conversely, those receiving the Bachelor's degree increased from 43 to 60 per cent of the total.

It is of further interest that an additional school, the University of Washington, was accredited jointly by the N.O.P.H.N. and the N.L.N.E. for the basic professional curriculum, qualifying the graduates for staff level positions in public health agencies that provide direct nursing supervision. Due largely to the additional school, graduates of such programs increased 40 per cent. One school in this group granted one-half of all the Master's degrees reported for all schools during the current academic year.

INCREASED TRAINING FACILITIES NEEDED

It is generally recognized that many of the students in graduate courses, especially medical administrators, are receiving further training for public health positions they already hold. Nor do the

existing schools have facilities for giving graduate training to a substantially larger number of students than they already have.

By 1950 it is expected that the School of Public Health of the University of Pittsburgh will be ready to train 50 or more graduate students annually. The Committee on Professional Education will study plans for one or more additional schools of public health located in strategic areas.

UNDERGRADUATE TRAINING IN ENVIRONMENTAL SANITATION

In order to have more definite information than has hitherto been available as to facilities for the training of persons who could fill positions in environmental sanitation in state and local health departments, a special study of baccalaureate degrees in sanitary engineering and sanitation has been made for the committee by the American Public Health Association Engineering Section Project. Recruitment of environmental sanitation personnel must start at the undergraduate level if present shortages are ever to be overcome. Furthermore, although it is recommended that sanitary engineers, most particularly directors of divisions, should have training beyond the baccalaureate level, presently many positions are filled by engineers and sanitarians without this additional training.

Questionnaires asking for information on baccalaureate degrees offered and granted and students enrolled were sent to 69 universities and colleges, the majority of whose civil or sanitary engineering curricula have been accredited by the Engineers' Council for Professional Development, a conference of national engineering bodies. Replies were received from 56, or well over three-fourths of the total. Of these, 33 reported that baccalaureate degrees were offered to students preparing for sanitary and public health engineering.

A like number of schools received questionnaires concerning sanitarian training leading to a baccalaureate degree. Of 51 replying, 7 reported offering degrees for students preparing for sanitation work on a non-engineering basis.

In reporting the number of students enrolled, the schools were asked to report only upper classmen, since academic work in the earlier college years is more general than specialized.

In analyzing the material it has been assumed that B.S. (Civil Engineering) reported offered by one school and granted to 12 students is the same degree as B.S. in Civil Engineering. Other consolidations could undoubtedly be made without doing violence to existing facts.

The 33 schools reporting sanitary engineering degrees, offered a total of 11 separate baccalaureate engineering degrees, 7 of them B.S. or one of its variants. The 6 sanitation degrees offered by the 7 schools were all B.S. or its variations.

The schools reported 352 sanitary engineering students and 67 sanitation students enrolled for baccalaureate degrees. Among the former, the largest number of students, 46, was reported by Manhattan College; only 5 other schools had 20 or more students, and 16, fewer than 10 students.

Nearly 40 per cent of those enrolled. 138 students, received public health or sanitary engineering degrees. Of the 22 schools graduating students, 12 gave degrees to fewer than 5 students, and only 6 to 10 or more. Of the 138 degrees granted, 65 were the B.S.C.E. degree (written B.S.(C.E.) or B.S. in C.E., for 50 students in 9 schools and B.S. in C.E. (Sanitary Engineering) for 15 students in 3 schools); 36 students received the B.C.E. degree (10 of them in one school with Sanitary Option as a part of the degree). No school reported offering more than one degree in the

sanitary engineering field. Thus it would seem that the desired consolidation of degree titles in the undergraduate field might be more readily accomplished than in the graduate area.

Six different degrees were offered by the 7 schools preparing students for sanitation work on a non-engineering basis, and again no school offered more than one degree. Of the 6 degrees offered, only 3 were granted in 1947–1948, B.S. to 19 students, B.S. in Sanitary Science, and B.S. in Bacteriology and Public Health, each to 4 students.

Perhaps the most discouraging fact revealed by this exploratory study is the limited source of students upon which the schools training graduates of public health engineering can draw. Nearly as many graduate as undergraduate sanitary engineering students were enrolled and more graduate than undergraduate degrees granted. It would appear, therefore, that the students doing graduate work are being drawn from other occupations, although one must not overlook the possible lingering effects of the war period dislocations. Whatever may be their influence, however, the necessity for active recruitment among undergraduates and even among high school students is unmistakable.

The questionnaire on undergraduate courses included an inquiry about the extent of vocational guidance given to underclassmen. Of 45 universities reporting, 36 reported vocational guidance and 9 did not give guidance. In 30 instances, these students were advised of the educational requirements for sanitary engineering and in 9 they were not. Forty of the universities gave underclassmen information on career possibilities open to the sanitary engineer, while 4 did not. Several universities reported that apparently career opportunities were not being sufficiently emphasized to attract students to sanitary engineering courses. Although the significance of this inquiry is limited, it again points to the fact that neither the engineering nor the public health professions are giving high school and early college students sufficient information about the rewarding possibilities of a sanitary engineering career.

1949–1959

NOW that the election is over and the smoke of conflict has begun to clear away it is possible once more to consider public issues on their merits and without reference to their effect on the fate of candidates or parties. To the readers of this *Journal,* the future of public health in these United States is a public issue of paramount importance; and it is fitting that we should give serious attention to a document published last September and consider its significance for a nation which has passed through the throes of a Presidential conflict, and should now be ready to discard partisanship and prejudice and plan for united efforts to promote the welfare of the American people.

We refer, of course to the report of Oscar R. Ewing, Federal Security Administrator entitled "The Nation's Health: A Ten Year Program." This report is based, for the most part, on the deliberations and unanimous conclusions of the National Health Assembly of last May; and has already been reviewed in our "News from the Field"[1]; in which review the nine major health goals outlined in the report are listed in some detail. These goals are of three general types. There is first, essential need for increased personnel and facilities. Mr. Ewing estimates that we shall require by 1960, 600,000 more hospital beds than we now have; and that the output of our medical schools must be increased by 40 per cent, and that of our dental schools and nursing schools by 50 per cent, if we are to reach minimum standards by that year. In the field of public health administration, complete coverage of all areas with basically equipped health units is, of course, held to be essential. The report, in the second place, emphasizes the need for expanding health services of all kinds to include competent challenges to problems now unmet, such as complete programs for child health, for mental health, and for care and rehabilitation of chronic disease. For attainment of the ends outlined above, it is suggested that our governmental expenditure for health (federal, state, and local) be increased from its 1947 figure of slightly under $2 billion to slightly over $4 billion; and indicates a saving of $27 billion a year from possible resulting economies in life and health.

Mr. Ewing's third major objective is to eliminate the economic barriers which now prevent the outstanding potentialities of American medicine from reaching in full measure the groups which are most in need of them. He emphasizes the fact—so familiar but so commonly ignored—that (in 1946) 28 per cent of our families had family incomes below $2,000. He believes that we must "assure that every individual without regard to his economic status has full access to adequate medical services for the prevention of illness, the care and relief of sickness and the promotion of a high level of physical and mental health."

This objective obviously implies—in addition to provision of standard preventive service—that some way must be found for securing those individual medical services for which the family of modest income cannot possibly budget, and for providing such services on a basis which preserves the self-respect of the household without labelling them as paupers.

To attain this end, it is obvious that some form of orderly prepayment is essential. Mr. Ewing quotes with approval the conclusion of the National Health Assembly that "The principle of contributory health insurance should be the basic method of financing medical care for the large majority of the American people, in order to remove the burden of unpredictable sickness costs, abolish the economic barrier to adequate medical services and avoid the indignities of a 'means test.'" Many plans of this kind are operating on a voluntary basis; but Mr. Ewing points out that as a rule, the benefits which such plans offer are limited in scope; that the plans cover only a small proportion of the people; and that it is almost impossible that they could ever reach the lower half of the population, from an economic standpoint. He therefore, in this report, goes in this one respect, beyond the conclusions which the Health Assembly was able to reach with unanimity; and advocates a national health program of prepaid health insurance which will mobilize the total group-purchasing power of the people in the interest of all. The plan which Mr. Ewing proposes is a gradual and highly flexible one. It includes a preparatory "tooling up" period and the beginning of actual service only after three years, and then including at first, only such services as existing resources permit and with coverage as broad as may seem practicable at the time. Actual operation would, of course, be decentralized to the states; and complete freedom of professional personnel explicitly assured. The report analyzes various objections to such a program, the bogies of "socialization" and "compulsion," the question of adequacy of personnel to carry out the plan (a serious and important one), the cost of the program and its possible effects on quality of service (another most vital problem). We urge all thoughtful students to read these pages of the report.

Mr. Ewing points out that success in this—or any other—program will depend on community understanding and community support. The role of the federal government in health is to provide for leadership and coördination and to fill gaps which cannot be filled by state and local action. Therefore he makes the sound and fruitful suggestion that state and local health assemblies be called throughout the nation to follow the pattern of the highly successful National Health Assembly of last May. Such assemblies should form the best possible basis for local health planning and for intelligent support of whatever federal legislation is essential as a framework for state and local progress.

"PUBLIC HEALTH REPORTS" FOR OCTOBER 8, 1948

THE weekly bulletin of the U. S. Public Health Service is, of course, a familiar and essential source of information to every student of public health. One particular issue which appeared last fall contained two articles of such significance as to deserve special notice.

One of these articles, by I. M. Moriyama, discusses the apparent increase in mortality from diabetes in the later decades of life which has occurred in recent years. Since Banting and Best discovered insulin in 1922, the diabetes death rate at ages over 64 years has more than doubled; and as Moriyama points out this is chiefly due to the system of automatic allocation of joint causes of death. When, for example, heart disease was reported by the physician as a primary cause of death with diabetes as a contributory cause, the system of priorities accepted by statistical offices credited the death to diabetes. As a result, the more effectively diabetes was controlled by insulin, the more diabetics would live to old age to die of heart disease; and the more rapidly the recorded death rate from diabetes would increase. In the present year, a new procedure adopted by the International Conference for the Sixth Decennial Revision of the *International Lists of Diseases and Causes of Death,* held in Paris last April, will go into force, placing more direct responsibility on the physician for determining the actual cause of death.[1] Our future statistics will show unfortunate breaks with past trends but they should be of far greater significance.

A second paper in this same issue of *Public Health Reports* is a well planned epidemiological study of the influence of a fly control program on diarrheal diseases by James Watt and D. R. Lindsay. In a district of the Rio Grande River Valley of Texas, the population was divided into two approximately similar and nearly equal areas. In the towns of Group A a vigorous program of fly control was initiated in April, 1946, and continued until August, 1947. In the areas of Group B such a program was initiated in September, 1947 (when it was discontinued in the towns of Group A), and continued to February, 1948. The index of fly prevalence in Group B ran continually above that of Group A until the shift in procedure. In both summers it reached a maximum seven times as high as that for Group A. When the fly control program was transferred to the Group B area, the lines crossed at once and for the late fall of 1947, flies in Group A areas were nearly ten times as numerous as in those of Group B. Parallel examination of stools in the two areas showed 1.9 per cent of stools yielding *Shigella* organisms in Group A while it was protected as compared with 4.2 per cent for Group B. After fly treatment was transferred to Group B, this area showed only 2.4 per cent of such infection as compared with 2.5 per cent for Group A. Attack rates of diarrheal diseases among children under 10 years of age showed exactly the same curve, with higher rates for Group B than for Group A so long as Group A was fly protected and a reversal of the situation when fly control was shifted to Group B. Finally, precisely the same relationship was shown with regard to reported deaths from diarrhea and dysentery in children. This is an unusually neat and adequate example of competent experimental field epidemiology.

Our fraternal congratulations to the Editor of *Public Health Reports* on this admirable issue.

WHY IS AN ALCOHOLIC?

THE growing interest in alcoholism as a psychosomatic rather than a moralistic problem will be strengthened by a recent study from the University of Southern California. Dr. M. P. Manson has developed, after extensive preliminary study, a group of 72 questions designed to reveal certain significant differences in personality; and, in a final phase of the study, the response to these questions was recorded for 268 alcoholics and 303 nonalcoholics. The 2 groups revealed distinct and statistically significant differences with regard to seven personality characteristics, anxiety, depressive fluctuations, emotional sensitivity, feelings of resentment, failure to complete social objectives, feelings of aloneness, and poor interpersonal relationships. The alcoholics showed markedly higher scores on these points than the nonalcoholics, and taking a given total score as a dividing line, 4 out of 5 of the total group of 571 persons would be correctly classified as either alcoholic or nonalcoholics by the test above.

The study seems a competent and promising one, and deserves serious attention and repetition. We must leave to the psychologist the question as to how far emotional problems lead to excessive drinking, and how far the reverse relation may obtain; but the fundamental nature of the personality traits revealed would seem to indicate the former relationship.

Clearing House on Public Health Salary Information

1948 STATE SALARY STUDY

The second annual study of salaries of public health personnel in state health departments was published in October, 1948, by the Public Health Service in coöperation with the Association of State and Territorial Health Officers and the American Public Health Association. It is based on reports from the 48 states reporting nearly 6,000 professional workers and representing all the professional groups usually employed in state health departments.

The salary figures are for August, 1948, nine months later than the time of the first study. In that period median annual salaries had increased by $400 for medical and sanitation (non-engineering) personnel, by $200 for sanitary engineers, laboratory personnel, supervisory and consultant nurses, and nutritionists, and by $100 for staff level public health nurses and graduate registered nurses.

Although 4 state health officers were receiving less than $6,000, more than one-fourth were receiving $10,000 or more. The 14 states paying $10,000 or more are northern, southern, eastern, western, industrial and agricultural, and both thickly and sparsely settled. One state health officer serving a population of less than a million received the same salary as one serving nearly 10 million.

The median salary of state health officers was $7,500 paid by 5 states. Thirteen state health administrators received less than $7,000. The average annual salary was $8,247, an increase of $622 over that of November, 1947.

Among the directors of specialized medical services, the highest annual salary reported was $12,000 for a director of tuberculosis control activities. Next was a state director of local health service at $11,000. The salary of no other medical specialty director was as much as $10,000. The lowest salary paid in this category was $4,500 in 2 instances. Average salaries for the various categories of workers are shown in the Table A below. It will be noted that of four groups, salaries of directors of local health services had the highest average, those of directors of maternal and child health services the lowest.

TABLE A

Increase in Average Salaries for Program Directors

Position	*November, 1947*	*August, 1948*	
		Amount	*Percentage Increase*
Health Officers	$7,625	$8,247	8.2
Directors of Local Health Services	6,695	7,354	9.8
Directors of Maternal and Child Health Services	6,264	6,829	9.0
Directors of Venereal Disease Control Activities	6,407	7,017	9.5
Directors of Tuberculosis Control	6,643	7,311	10.0
Directors of Public Health Dental Services	5,714	6,211	8.7
Directors of Sanitary Engineering	6,117	6,528	6.7
Directors of Laboratory Services	6,095	6,394	4.9
Directors of Public Health Nursing	4,414	4,722	7.0
Directors of Vital Statistics	4,546	4,802	5.6

Average salary increases of medical administrators of specialized health activities during the nine month period ranged from 9 to 10 per cent while those of health officers averaged 8 per cent. The smallest increase of 5 per cent was found among directors of laboratory services and the lowest salaries for directors of public health nursing.

A study of the details of salary levels in the various regions of the country as divided into U. S. Public Health Service regions indicates that salary levels among the various groups in the public health profession have no consistent relation to each other. The Pacific states, for example, which have the highest median salary range for medical personnel, have the lowest for sanitary engineers. Southern states reported the highest median health officer salaries but the lowest for nursing and sanitation personnel.

It is obvious that a mosaic of factors determines salary levels for various groups in each state. An analysis of that mosaic into its components and the discarding of irrelevant factors is the goal of a further study in prospect, the purpose of which is to find common denominators for the various job titles.

The current study is available in limited quantities from the American Public Health Association. It is a valuable tool for administrators who are recruiting personnel. However, it should be borne in mind that these are raw data and must be studied in relation to the region of the country, the state's program, the going professional salary scale, and many other items.

COST OF LIVING FIGURES

The *United States Municipal News,* published by the U. S. Conference of Mayors, included in its December 1, *1948, issue (15:23)* a summary of cost of living figures, analyzed into components such as food, clothing, etc., for every year beginning with 1939, and monthly for September, 1947–September, 1948. This shows that the cost of living has almost doubled since 1939, 40 per cent of the increase having taken place since August, 1947. Food and clothing show the largest increases, rent the smallest. The neat little compact table of these figures is a handy gadget to have in reserve when discussing recruitment matters with county commissioners or state legislators. The figures, of course, are those of the U. S. Bureau of Labor Statistics. *United States Municipal News,* 730 Jackson Place, Washington, D. C.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

Society as the Patient—*By Lawrence K. Frank. New Brunswick, N. J.: Rutgers University Press,* 1948. 395 pp. Price, $5.00.

Lawrence Frank has brought together 30 of his articles published in professional journals over a period of 25 years. They range over the fields of economics, social psychology, education, the arts and the sciences. A critical reading of these essays furnishes an illuminating picture of the ideas and proposals of a man who is considered one of our leading social philosophers. Public health workers will be interested particularly in his concepts of the "etiology," "diagnosis," and "treatment" of our social problems—especially mental health.

He has adopted the concept of a sick society in need of treatment in order to simplify (or oversimplify) the discussion of a multiplicity of social problems each demanding special attention. He arrives at the rather startling "diagnosis"—"That we can view all of them as different symptoms of the same disease." The book abounds in such bold generalizations that it is provocative as well as profitable reading.

Two of the essays furnish keys to the author's diagnosis of our social ills—"Society as the Patient" and "Dilemma of Leadership." These essays present a gloomy, melancholy picture of our culture. It requires optimism not to be convinced that the "patient" (society) is not "sick unto death," and that we lack any leaders who are not driven by their frustrations, compulsions, and sense of guilt to seek personality fulfillment through exploitation of society. We disagree on both counts—even though we accept the accuracy of many of the examples cited. The difference of opinion lies in the breadth of the generalizations derived from them. For the author so classifies the majority of leaders in politics, business, industry, finance, the professions, education, and religion. He absolves them from personal guilt and places the responsibility upon our disintegrating culture.

Among the important determining factors (according to Frank) in this cultural disintegration are the competitive system and the distorted personalities created by the ineptness of our practices for socializing the child in the home and the school. The "treatment" prescribed is the reconstruction of our culture and the creation of a new design for living.

The essays of greatest practical usefulness to public health workers are those concerned with education and mental hygiene.

The reader may be surprised to learn that Frank chooses the psychiatrist to be the best *social diagnostician,* the artist as the outstanding *social teacher,* and the historian as a valuable *social therapist.* One may disagree definitely with some of the views expressed but they compel one to re-appraise both thinking and practice. This is a wholesome exercise if we follow the advice of Lyman Bryson in his foreword to "treat all of Mr. Frank's materials with rigorous caution." WALTER H. BROWN

Psychobiology and Psychiatry—*By Wendell Muncie. (2nd ed.) St. Louis: Mosby,* 1948. 620 pp. Price, $9.00.

The second edition of Dr. Muncie's book is, like the first, intended primarily for the use of medical students. It has three main divisions: Psychobi-

ology—the study of normal behavior; psychiatry and pathology — abnormal behavior; and treatment. The author omits child psychiatry, but otherwise the volume covers the psychobiology and psychiatry courses given at The Johns Hopkins Medical School. Dr. Muncie has undertaken to present the teachings of Adolf Meyer, with some modification based on his own experience in private practice.

The task of presenting psychobiologic psychiatry is difficult because this school of thought offers no systematization to explain everything comfortably. Self-characterized as "eclectic and pragmatic," it lacks the order and appeal of the Freudian school, for example. The presentation of dynamic concepts of disease, its diagnosis, prognosis and treatment, call for a high order of teaching and writing. That this book is difficult to understand is only partly attributable to the difficulty of the concepts, however. It is true both of Dr. Muncie and Dr. Meyer that in the translation of their thoughts and teachings into writing, a lack of simplicity makes it hard for us to gain the understanding that undoubtedly would come from personal contact with these men.

Part I, psychobiology, is written around an outline and guide for the student's study of his own personality. This would seem to be an effective means of capturing and holding the interest of the student, but much of the good effect is lost through the author's polysyllabic, professorial style. This section would gain in interest, too, if more information were given the reader not associated with The John Hopkins Medical School as to how the student's personality study is presented and evaluated.

The 377 page section on abnormal behavior, Part II, begins with an explanation and defense of psychobiologic psychiatry, includes an instructive chapter on examination methods, and systematically covers the field of abnormal behavior. The various disorders are well illustrated by case records. It is regrettable that Dr. Muncie has made a sharp separation between disease and its treatment. The section on treatment, Part III, is a helpful survey of general methods and the management of "specific" disorders, and deserves a separate place in a book such as this. However, excellent teaching opportunities have been lost by failure to relate treatment more closely to pathology. The effect on the reader is an impression of an almost nihilistic theory of treatment in view of the doctrine of psychobiologic psychiatry, which places emphasis on meeting the problem at hand with whatever method seems most likely to produce good results, and which does not rely on any special scheme of explanation or treatment.

In general this is a useful book, bringing a good deal of common sense and a reasoned perspective to what is still a too vague field. It should find its greatest use and popularity in undergraduate medical teaching.

PAUL A. LEMBCKE

Diagnostic Bacteriology—*By Isabelle Gilbert Schaub and M. Kathleen Foley. (3rd ed.) St. Louis: Mosby,* 1947. 532 pp. Price, $4.50.

This is a revised and enlarged edition of a text previously titled *Methods for Diagnostic Bacteriology,* originally compiled as a manual of methods for bacteriologists in diagnostic and autopsy laboratories of The Johns Hopkins Hospital and School of Medicine.

The first chapter presents technics for the use of agar plate media for the isolation and purification of cultures, and includes a section on the rapid paper disc method for determining susceptibility to penicillin and streptomycin. A long chapter then outlines procedures of choice for culturing specific pathogenic or autopsy materials or in

examining such materials for specific organisms. A chapter is devoted to detailed descriptions of the colony characteristics of pathogenic organisms with special emphasis on blood agar plate cultures. Next is a series of chapters giving the biological characteristics useful for the identification of pathogenic organisms with a series of schematic charts giving the differential characteristics within the various groups of bacteria. The unusual amount of space devoted to agar plates and colonial characteristics is based on the belief that a careful study of agar plates in connection with a knowledge of the source of the material and the organisms most likely to be found at such a site will frequently enable the medical bacteriologist to identify tentatively pathogenic organisms within 24 to 48 hours.

Part II of the manual deals with serological methods, detailing technics for the identification of cultures by agglutination and precipitin tests and for the examination of patients' sera by agglutination tests. No mention is made of the use of complement-fixation tests for these purposes. The final Part III gives formulae for media, stains and reagents, and directions for their use.

The text is well organized, with cross-references clearly stated, and with page numbers and references to original literature inserted in the body of the text. The fact that it is a methods manual is emphasized by every other page being left blank.

Although this manual is primarily for the hospital laboratory, its approach and methods are equally applicable to the diagnostic division of the public health laboratory. E. K. KLINE

The Abnormal Personality—*By Robert W. White. New York: Ronald Press*, 1948. 613 pp. Price, $5.00.

Among other chapters, this volume contains the following: Origins of Abnormal Psychology; Examples of Disordered Personalities; the Development of Personality; Fantasy, Dreams, and Hypnotic Behavior; Anxiety and Defense; Neurotic Conflict; Psychotherapy; Delinquent Behavior; Psychosomatic Diseases; Abnormal Conditions in the Brain; the Psychoses; Schizophrenia, etc.

The author of this book wants it to be known as a textbook, and a very useful one it is. Not only the student of psychology will benefit greatly from perusing it. but also the general practitioner of medicine who has not specialized in psychiatry. Indeed, it should be of great help to the public health officer and to any intelligent and cultured layman who wishes to become acquainted with the anomalies of human thinking. It is clearly, simply, and beautifully written and brings the subject up to date. Its introduction on the development of psychiatry is splendid. The book describes the abnormal personality from all angles. The author deserves particular credit for not having forgotten, as others so often do, the social and economic viewpoint both in the causation of the abnormalities and in the frequent hints as to the remedial measures. The examples from life, either original or quoted from the literature, are well selected and perfectly illustrate the theoretical text. The one dealing with the criminal boy who, trapped in delinquency through his home life and his later relationships, is pathetic and absolutely true. The last section, "The Problem for Society," will be particularly interesting to anyone who thinks along broad lines: "The problem of disordered personal reactions is one that cannot be solved without reference to the society in which they occur," is its first sentence.

The reviewer feels that some descriptions, like that of hypnosis, are unnecessarily elaborate and misses the following: a chapter on the normal personality or perhaps a good explanation as to

what personality is; also, although not strictly related to the topic, one regarding mental deficiency; a consideration of the lighter, the very light transition cases between mental health and mental disease; and finally, something about abnormal group or mob abnormal psychology. Nor can we fully agree with the definition that the "distinguishing mark of psychosis is an almost complete loss of contact with the surrounding world," which is exaggerated. And again, we believe that the author is wrong in trying to replace the expression "psychoneurosis" by "neurosis," these being really two different terms.

B. LIBER

Sanitation for Food Handlers and Sellers—*By Berl Benmeyr. Los Angeles: The American Institute of Sanitary Science,* 1948. 126 pp. 123 illus. Price, $4.95.

Instruction of foodhandlers, carried out by departments of health and departments of education during the past 10 years have been effective in sensitizing these much criticised and not easily forgotten employees to the careful and safe methods of storing, preparing, and serving of food. The instruction has varied from short talks or incidental information, to study groups, clinics, and short courses. The inevitable outgrowth of these various methods of foodhandlers' training has been the home study course devised by Berl Benmeyr in this paperbound booklet, which is amply illustrated with cartoons and intended primarily for restaurant owners, operators, and the employed foodhandlers.

The book is divided into four parts, each part followed by a series of questions of the true and false variety. The text is written so that it can be understood by the average porter, dishwasher, chef, waitress, or manager and proprietor. In many instances the author minces no words. Sections are devoted to the prevention of food spoilage and food poisoning, dishwashing, personal hygiene, lavatory and hand washing facilities, equipment construction, how to make friends and influence the health inspectors, and other worth while subjects.

For those health officers who desire to start foodhandling courses or who want to change their present procedures of instruction, the booklet is recommended. For the proprietor of the restaurant, tavern, drive-in, lunch room or similar establishment who wants an easy way to instruct his employees in correct sanitary procedures, the booklet is also recommended.

The paper binding, 8½" x 10¾" size, and lack of a table of contents and index do not enhance its use.

The author has to some extent pointed the information to West Coast foodhandlers and has limited his instructions to restaurant employees. There is a need for a book of this sort for use by all types of foodhandlers, not only those in a portion of the food industry.

FERDINAND A. KORFF

Motivation in Health Education, Report of the Annual Health Education Conference of the New York Academy of Medicine, 1947. *New York: Columbia University Press,* 1948. 53 pp. Price, $1.00.

As Dr. Donald B. Armstrong states in the foreword, "The theme of this small volume embraces one of the most important problems in education. How can the educator make his instruction effective in the behavior of those whom he teaches?"

This volume consists of four provocative discussions by outstanding leaders in health education, psychiatry, and anthropology. The subjects discussed include The Problem of Motivation in Health Education, by Dr. Iago Galdston; The Changing Patterns of Motivation, by Dr. W. W. Bauer; Myths

and Resistances in Health Education, by Dr. Lawrence S. Kubie; and Positive Motivations in Health Education, by Dr. Margaret Mead.

This compact volume will appeal to the reader as a stimulant toward further study and exploration of the problem of motivation in health education.

A. HELEN MARTIKAINEN

The Rockefeller Foundation — A Review for 1947—*By Raymond B. Fosdick. New York: The Rockefeller Foundation,* 1948. 64 pp. Free on request.

This is a masterful review of an outstanding philanthropy during a critical year. It recounts the expenditure of more than 23 million dollars during 1947, which sum exceeded the Foundation's income from investments by 13 million dollars. Included in these appropriations are one of 10 million dollars for the China Medical Board and one of 3 million for social sciences (both of them exceeding the 2¼ million appropriated for public health and 1½ million for the medical sciences).

Those familiar with President Fosdick's style will want to read the text itself which is one of the best oriented statements of our world condition known to the reviewer. "The issues of our time and of human destiny," says Dr. Fosdick, "will be determined, not at the physical, but at the ethical and social level."

Dr. Fosdick uses the activities of the World Health Organization as a pertinent illustration of how medicine and health overpass national boundaries. "Public health work carries no threat to anybody, anywhere. Cancer and scarlet fever have no political ideology . . . the principles of sanitary engineering do not bear a Russian or an American label." Dr. Fosdick believes that the present is one of the supreme moments of challenge, in which the character of our response determines the chances of survival, and he proceeds to illustrate how the Rockefeller Foundation used its funds and its experience for the benefit of mankind throughout the world. This is highly recommended reading. REGINALD M. ATWATER

Health in Schools — Twentieth Yearbook. *(5th ptg.) Washington, D.C.: American Association of School Administrators,* 1948. 400 pp. Price, $1.50.

First issued in 1942 and now in its fifth printing, this *Yearbook* is meeting a real need. This is an important publication, especially since it is an official document from the American Association of School Administrators. Official and voluntary health agencies will find much of interest in this book. The official point of view of school administrators regarding school health is outlined in considerable detail. Emphasis is placed upon development of a school health program which benefits all children and utilizes all the resources within the community.

Of particular interest to health officers and school administrators alike is the point of view expressed on page 300:

> In the field of education the school cannot delegate its responsibility. Society is demanding that its activities be extended to groups both younger and older than the traditional school-age groups. The health department concerns itself with the health education of another part of the general public. For the health department to say that everything that has to do with health must be administered by it, and for the school system to say that all education in the community must be administered by it, would be equally absurd. On the other hand, the health department must be concerned with the professional quality of health services carried out in the schools, and the school system must be concerned with the educational outcomes of those same services no matter which agency employs the personnel.

Written six years ago, some of the references, especially those relating to federal agencies, are out of date. However, the basic philosophy and the pro-

cedures described in the book are sound and are fundamental to the development of good school health programs. Everyone interested in the health of school age children is urged to study this *Yearbook.* S. S. LIFSON

Safety for the Household. *U. S. Department of Commerce, National Bureau of Standards, Circular 463. Washington, D. C.: Gov. Ptg. Office,* 1948. 190 pp. Price, $.75.

Unique in being the most complete work yet published on home safety, this handbook fulfils a need for an authentic text.

Presented on the academic level in a style readable for the average householder as well as for the student, this book can serve as a guide for the use of public health nurses, family social workers, and others who are in a position to observe family practices and the environment of the home.

Contents of the book are divided into such classifications as Chemical Hazards, Electrical Hazards, Fire Hazards, Gas Hazards, Lightning, Mechanical Hazards, Yards and Gardens, Suggestions for Building a Home. The introduction gives a measure of the problem and deals with the organized movement, and a list of sources for materials. A check list of 44 questions is included.

In their introduction the authors call attention to their aim in the book, which is not to cause undue anxiety but rather to suggest means of removing causes for alarm. "Caution alone is not enough," state the authors, "because many of the dangers are not commonly known." New types of equipment for the home; miniature engines so widely used in toys; radio and television sets, and other devices which call for high voltage circuits, all place upon the modern householder a responsibility for extending his information about the prevention of accidents.

Paper covers in the shade of green used for safety, clear type, sketches and a good grade of paper add to the book's inviting appearance and readability.

ETHEL M. HENDRIKSEN

A Guide to the Selection and Training of Food Service Employees —*Prepared by a Committee of the Food Administration Section of the American Dietetic Association. Minneapolis: Burgess Publishing Company,* 1947. 47 pp. Price, $1.50.

This manual is a guide for dieticians and food service directors. It should be of particular interest to dieticians, because in part it clearly outlines the administrative position of the dietician as the supervisor of a food service program. The guide is divided into two parts; Part I, Preparation for a Training Program, and Part II, The Training Program.

The first part of the manual is expertly worked out and should be of value to any food manager. It outlines job requirements, methods to select employees, how to determine worker requirements, and includes sample illustrations of employment applications, interview forms and record forms.

Part II, The Training Program, includes methods of training, job relations, use of equipment, cooking methods, food standards, sanitation and a valuable reference list, including sources of visual aids.

Essentially this is a preliminary study of the problem of selection and training of food service employees. Its general form should accomplish the purpose for which it was written, as a basis for the development of a more detailed manual. It is, however, necessary to add that competent public health consultation should be sought by the American Dietetic Association, before attempting to construct a more detailed manual. For example, the authors have led the reviewer to believe that they are not familiar with the limitations of physi-

cal examinations. A few minor points on personal hygiene and sanitation are open to question. In general, however, this is an excellent guide for the purpose for which it was intended.

WALTER S. MANGOLD

The Chemical Composition of Foods—*By R. A. McCance and E. M. Widdowson. (2nd ed.) New York: Chemical Publishing Co.,* 1947. 156 pp. Price, $3.75.

The first edition appeared in 1939 and has had three reprintings, attesting to the value of the book and the necessity of a new edition. This book supplies data in the form of tables, two sets of which are included; the first lists composition per 100 grams, while the second tabulates compositions per ounce. The constituents listed include water, sugar, starch and dextrins, total nitrogen, protein, fat, available carbohydrates, and calories; sodium, potassium, calcium, magnesium, iron, copper, sulphur, phosphorus, and chlorine; acid-base balance expressed in cubic centimeters of one-tenth normal solution. About 540 British foods are analyzed. These include many cooked foods, the recipes for which are given. This is undoubtedly one of the most complete and up-to-date books on food composition that have come to the reviewer's attention. Data on vitamins are not included. The book is excellently indexed.

CARL R. FELLERS

Health Center Buildings—*By Harry E. Handley. New York: Commonwealth Fund,* 1948. 48 pp. illus. Price, 50 cents.

Community leaders interested in experience in rural health centers with regard to location, space requirements, architectural design and use of the building, will welcome the Commonwealth Fund's excellent report on these phases of its now completed program of health demonstrations.

The report, in brief form, deals with the general purposes and local control of the Fund centers, with design and equipment of the buildings and considerations in planning a health center.

The report gives a summary of information concerning each of the several centers and the area they serve. Tabulations give such information for each area as the number of square miles, population, the number of physicians, dentists, hospital beds, health department budgets, and per capita costs.

There is a drawing and floor plan for each building, together with a summary of the essential facts, such as births, deaths, principal sources of income, medical and hospital services available, special health problems, health department staff and cubage, construction costs, and area of the buildings.

An appendix to the report gives data obtained from questionnaires on the use of the first six Fund centers. This is of special interest since it presents practical criticisms and suggestions by health officers and others based on their administration and use of the buildings.

KENNETH D. WIDDEMER

Thyroid Enlargement and Other Changes Related to the Mineral Content of Drinking Water (with a note on Goitre Prophylaxis) Medical Research Council Memorandum No. 18—*By Margaret M. Murray, J. A. Ryle, Beatrice W. Simpson, and Dagmar C. Wilson. London, Eng.: His Majesty's Stationery Office,* 1948. 39 pp. Price, Ninepence net.

This painstaking and scientifically accurate study, carried out in the British Isles is a real contribution to our knowledge of food deficiencies.

The method of examination for thyroid enlargement and its classification is satisfactory for such clinical studies. However, instead of using such terms as "physiological goiter," it would be more accurate to teach that: There are

periods, such as puberty and rapid growth, pregnancy and gestation, or illness and malnutrition, when the "physiological demand" for thyroid hormone and iodine is greatly increased, thereby causing a depletion of thyroid hormone, and this condition produces the physiological changes in the gland of cellular-hyperplasia and glandular hypertrophy or goiter. This deficiency of thyroid hormone is always due to a lack of iodine, and if the gland is kept supplied with this fundamental food element it can meet all of the increased physiological demands without undergoing any of the above described histopathological changes or goiter.

The distribution of goiter throughout England, Ireland, and Scotland corroborates the findings in this country; that is, areas of endemic goiter are found fairly close to the sea, which is contrary to earlier teaching.

In this survey the food iodine in any community was measured solely from the amount of iodine in the water supply. However, in some sections of the world food iodine is obtained from natural salt and this would not be estimated when only the drinking water is studied. In other sections food iodine from sea foods will be an important factor when endemic goiter is less than would be predicted from the iodine content of the drinking water.

Again the age old question is raised: Does the hardness of the water (a high calcium content) cause goiter? A high calcium content in the drinking water may, in some way, interfere with the utilization of the iodine, but it does not change the fundamental concept that goiter is due to a deficiency of available iodine.

The careful analysis for fluorine in the drinking water and the presence of fluorosis in certain localities, is a valuable contribution. The geographical distribution of mottled enamel or fluorosis in the United States has been fairly well established. The best known areas of fluorosis do not correspond to the areas of endemic goiter. There is always some overlapping with an occasional goiter in areas of fluorosis. However, there is practically no known fluorosis in our most severe endemic goiter district. Public health officials, who have studied both fluorosis and endemic goiter, state that the excessive fluorine, which produces the mottling of the teeth does not affect the thyroid, nor is it a possible factor in the etiology of endemic goiter.

We agree with the authors that iodized salt is the most efficient and practical method of prophylaxis of endemic goiter.

O. P. KIMBALL

Widening Horizons in Medical Education 1945–1946—*A Report of the Joint Committee of the Association of American Medical Colleges and the American Association of Medical Social Workers. New York: Commonwealth Fund,* 1948. 228 pp. Price, $2.75.

Prerequisite to treating the "whole person" is an understanding of his social and environmental background. Unfortunately the present trends in medical practice lessen the opportunity for clinicians to observe these factors directly. As there is an increasing number of visits to offices, clinics, and hospitals, there is a corresponding decrease in house calls and personalized service. The medical student is apt to have even less insight into the problem for he may never have seen a patient in his own habitat.

To cope with the dilemma of adequate medical-social teaching, the Association of American Medical Colleges in 1941 appointed a committee which later collaborated with the American Association of Medical Social Workers. This joint committee was not so much concerned with the ultimate objectives in training medical students, nor with a definition of the segment to be fulfilled by the professional social worker, as it

was with a survey of the teaching done in this field by medical schools throughout the country. From their report it is evident that some schools have well integrated plans of teaching the medical-social aspects of illness, but one must conclude that the field is seriously neglected in the majority. Those charged with the responsibility of educating the pre-medical student, as well as those teaching medical students, should profit greatly from the studies of the committee and find their suggestions invaluable in planning an adequate curriculum.

WILLIAM W. STILES

Advances in Food Research. Vol. I—*Edited by E. M. Mrak and George F. Stewart. New York: Academic Press*, 1948. 459 pp. Price, $7.50.

This book consists of ten reviews, reports, and articles by a dozen different authorities on various aspects of nutrition, food technology, microbiology, biochemistry, and other important subjects in the food field. Included is material on the factors affecting the aging of beef, the vitamin content of canned foods, the physiological basis of voluntary food intake, dried whole eggs, the palatability of poultry, processed potatoes, the influence of climate and fertilizer practice on the vitamins and minerals in vegetables, the browning of fruit products, food preservatives, and the deesterification of high-polymer pectins.

It is interesting to note, for example, that the location and season in which plants are grown have a profound effect upon their content of ascorbic acid, and that the amount of available sunlight is the most significant factor in the development of vitamin C in many vegetables, although other factors play a part in the production of this vitamin, as well as of carotene. In the light of these facts, some of the data in existing vitamin tables may have to be reëvaluated and possibly revised.

The book is well printed and has a good index, and each review is well documented. It should prove of great value to nutritionists, food technologists, and all others who are interested in or concerned with food research.

JAMES A. TOBEY

Best's Safety Directory (of Safety, First Aid, Hygiene and Fire Protective Products)—*(2nd Annual Edition), 1948. New York: Alfred M. Best Company, Inc.*, 1948. 494 pp. Price, $5.00.

The volume consists of 8 pages of introduction, 415 pages of directory, a 53 page geographical breakdown of sales offices and distributors of products listed, a 16 page index to products listed, and a 2 page index to advertisers. The directory itself is subdivided into nine major sections: Fire Protection (57 pp.), Personal Protection (137 pp.), Personal Hygiene and Sanitation (33 pp.), Plant Maintenance and Sanitation (54 pp.), Above-Ground Protection (27 pp.), Liquid and Solid Materials Handling (24 pp.), Atmosphere Control (28 pp.), Machinery Guarding and Control (28 pp.), and Training and Warning Aids (27 pp.). These nine major sections are still further broken down into about six further subdivisions, such as (under the heading Personal Protection), Respiratory, Head, Eye and Face, Arm and Hand, Body and Leg Protection.

A typical subdivision, that on Eye and Face Protection, contains its own introductory page, 16 pages of item listings, 2 pages of "Recommendations for Eye and Face Protective Products" and 14 pages of product advertisements. Each item listing, such as that for "Goggle-Eyecup-Chemical" consists of a one paragraph description and the customary list of names and addresses of manufacturers of this type of goggle. Photographs illustrating items listed appear on almost every page.

The directory is well printed and bound. The text, listings and indices are adequate for the purpose indicated by the title of the directory.

ARTHUR C. STERN

American Rural Life—A Textbook in Sociology—*By David Edgar Lindstrom, New York: Ronald Press,* 1948. 385 pp. Price, $4.00.

Workers in practical programs of health or welfare sometimes avoid literature labeled "sociological" because it is often highly conceptual or theoretical, not geared to everyday, local problems. They will not be bored with Professor Lindstrom's book, however. For this is a "textbook in sociology" which, while built on a firm theoretical foundation, provides a vital, almost journalistic account of the immediate problems of rural life in America and the measures being taken or proposed to meet them.

The theoretical core of *American Rural Life* is essentially that, with industrialization, the quality of rural culture is deteriorating. This creates a serious problem for the whole nation, since, with present urban and rural birth rates, the cities depend for their survival on migration of young people from the country. To preserve the best social values in rural areas, it is argued that the agricultural rôle of the family-size farm must be strengthened; on this economic base, improvements must be made in rural education, health services, recreation, social security, and all types of organized group activity.

In offering this program of action, Prof. Lindstrom presents abundant data on the current status and trends of the rural population, agricultural economics, and rural institutions (the family, church, school, etc.). The complex variety of governmental programs developed to support the farm economy are succinctly described, as well as the efforts of farmers' organizations and other voluntary groups. Prof. Lindstrom maintains strict objectivity in his diagnostic accounts, but his recommendations for treatment reflect a particular point of view. It is the view of the main body of liberal students of American agriculture today.

There is a chapter devoted to health in rural areas which, despite a number of inaccuracies, gives a useful sketch of current problems. It is perhaps imbalanced in its recommendations, devoting relatively excessive attention to school health services, for example, while making only passing mention of insurance against medical service costs. Throughout the volume references to the health implications of various economic, demographic, or social situations are frequent and incisive.

While designed primarily for students of rural sociology, this study can be a valuable source book for all public health workers in rural areas. It would be hard to find a volume which could so well orient the newcomer in rural health service on the total setting of rural life in which he works. As health agencies have awakened to the importance of gaining the widest community understanding of public health programs, books of this type become as indispensable as manuals of communicable disease control. MILTON I. ROEMER

Foods, Production, Marketing, Consumption — *By Jean J. Stewart and Alice L. Edwards. (2nd ed.) New York: Prentice-Hall, Inc.,* 1948. 490 pp. Price, $6.35.

In the preface to the first edition which was published in 1938, three reasons for writing a book of this type were given: to lead individuals to reach proper conclusions on food problems, to discuss controversial problems as far as a book of this kind can do so, and to point out where information on food topics may be obtained. How much such information is needed today by

many homemakers who are posing as authorities in the food field! The book is in three parts with thirteen appendices. Part one concerns the need for food by individuals and groups; part two, foods, production, nutritive value, and buying; and part three, principles of cooking foods. In the appendices is a wealth of information relating to nutritive value of foods, adequate diets, cooking temperatures, and on a few other practical subjects.

In a few places the authors have shown lack of close familiarity with the subjects they discussed. Certified milk is said to be raw milk. Most of it today is pasteurized. In their discussion of canning of foods it is stated that heating or "processing" is for the purpose of sterlizing the food so that all organisms which cause spoilage may be destroyed. The implication in this statement is that they are destroyed if the food keeps, which is not the case. They speak of "oven sterilizing" when "oven processing" would be better, because the term "process" is the term applied to heating foods in canning. It was introduced when it became known that heating canned foods did not sterilize them. They speak of "sterilization of canned products" when even commercial canners cannot sterilize canned foods and have had to introduce the term "commercial sterilization." They state that thermophilic bacteria are *probably* responsible for flat-sour spoilage. These bacteria *are* the causes of it. Tomatoes are considered to be acid foods not requiring processing under pressure. Most of them probably are, but some species are too near the neutral point to be processed in boiling water. Home canned tomatoes have caused quite a few outbreaks of botulism. The organism causing botulism is called "bacillus botulinus" when the accepted name for many years has been *Clostridium botulinum*. The authors define evaporated milk as the partially dehydrated product prepared from whole or skimmed milk. The Standard of Identity for Evaporated Milk under the Food, Drug and Cosmetic Act of 1938 stipulates not less than 7.9 per cent of milk fat. Skimmed milk can be evaporated but it cannot be called "evaporated milk." By mentioning these points the reviewer does not wish to detract from the value of the book. They happen to be in his special field of interest. Some of the difficulty is due largely to the fact that the authors have tried to cover a large field in a book to be used by students.

F. W. TANNER

Enjoy Your Child—Ages 1, 2, and 3—Public Affairs Pamphlet No. 141 —*By James L. Hymes, Jr. New York: Public Affairs Committee, Inc.,* 1948. 32 pp. Price, $.20.

The author and the sponsoring committee of this relatively short but excellent pamphlet designed for parents of very young children deserve congratulation. The author has presented essential psychological facts of the child's early emotional development in language and form so clear, natural, vivid, and convincing that both the facts and his "helpful hints" of the management of the problems incident to the 1, 2, and 3 year old age should find ready acceptance. Acceptance of the facts and acting upon his hints should, in turn, contribute greatly to the happiness and understanding of all manner of parents in relation to the runabouts in the family and would, indeed, constitute the soundest basis for mutual democratic understanding between all ages and kinds of people. The author has artfully combined serious fact with pleasant humor, and a dozen drawings by Scheib amusingly illustrate the sense and spirit of the text.

In his selection of characteristic behavior of 1, 2, and 3 year olds, Mr. Hymes has described apparently differ-

ent problems of different ages, but he skillfully develops the fact that these various reactions are all basically responses of healthy growth and can all best be solved by a "basically healthy attitude" of the parents. In addition, he successfully groups the main behavior characteristics of the 1 to 3 year olds under two main subjects (goals), independence and security. This bi-polar classification is remarkable not only for its apparent simplicity but because it really helps to clarify the reasons for the particularly contrary nature of the toddler.

Most noteworthy of all in this exemplary presentation is the author's introductory address to the parents as experts. His implicit trust in them as already experienced observers courts their confidence for his guiding suggestions. The encouragement of such sensitive and pedagogical trust in the expertness of parental observation will go a long way in fostering the recommended parental attitude of "unconditional love." EDITH B. JACKSON

Essentials of Fevers—*By Gerald E. Breen. (2nd ed.) Baltimore: Williams & Wilkins,* 1948. 351 pp. Price, $4.50.

This book is a pocket-size edition written for medical students and young practitioners to acquaint them with the essentials of the commoner communicable diseases or fevers. It is surprising to find so much information in so small a volume. In addition to consideration of 21 communicable diseases, there are four introductory chapters, a section on physical diagnosis, and a terminal chapter of miscellany, including diagnostic errors. Although the material is largely clinical, preventive and public health aspects of the various infections are also considered.

The style is lucid, pleasantly readable, humorous, and interspersed with trite remarks, the latter pointing up the text. However, inherent in the compend is the danger of generalities and on this score the work suffers. It also seems unfortunate to this reviewer that there is no bibliography and that the index is so cursory. Charts and tables are generously interspersed in the text and there are 16 colored drawings, which are inferior to colored plates, but in this instance are distinctive because they illustrate what is intended very well and, furthermore, are the handiwork of the author. The book cannot be recommended as a communicable disease text, but it is packed with practical, usable information, which should be of value to the groups the author wishes to reach. FRANKLIN H. TOP

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

! ! !—Veterans of our own Association's annual dinners will find enlivening this story of our British counterpart's comparable function. The Society's president toasted the King (duly honored). Then the Minister of Health toasted the Society. Then the President toasted the Minister. Then a county-borough M.O.H. proposed a toast to the guests. And two guests offered what I assume might be called countertoasts. Seems like a fine old custom, doesn't it?

ANON. The Annual Dinner. Pub. Health. 52, 1:13 (Oct.), 1948.

Supportive Evidence—In a well controlled study, the British research council's investigation finds streptomycin therapy effective in doing what the patient's tissues alone cannot do against acute progressive tuberculosis.

ANON. Streptomycin Treatment of Pulmonary Tuberculosis. Brit. M. J. 4582:769 (Oct. 30), 1948.

Obtaining Sickness Data—This is pretty obvious, but it needs to be said—and read. The urgency of the tasks facing social scientists, has led them to "get on with the job" instead of developing and testing surveying technics. Sound research in morbidity survey methods is loudly called for, says this British scientist.

BRANSBY, E. R. Some Aspects of Morbidity Surveys. Brit. M. J. 4579:678 (Oct. 6), 1948.

Rattus rattus norvegicus — Alberta, it is reported, is rat-free and Albertans propose that it shall remain the only extensive rat-free area in America. It isn't altitude or climate or vegetation that keeps the province rat-free: it is determination. Perhaps you'll want to read about this unique manifestation of common intention.

BROWN, J. H. Alberta: The Only Rat-Free Province in Canada. Canad. Pub. Health J. 39, 9:367 (Sept.), 1948.

Preliminary Report — Penicillin taken by mouth immediately after presumed exposure to gonorrhea proved highly effective in this controlled Navy study. This might be called making the world safe for indecency.

EAGLE, H., *et al.* Prevention of Gonorrhea with Penicillin Tablets. Pub. Health Rep. 63, 44:1411 (Oct. 29), 1948.

Your Attention, Please — There really *is* something new under the sun—at least new to these rheumy eyes. For ten years a doctor has been urging that babies be fed from the cup from birth. (Premies, too, are included.) He claims several advantages which you will have to go to the original article to learn about.

FREDEEN, R. C. Cup Feeding of Newborn Infants. Pediatrics. 2, 5:544 (Nov.), 1948.

Tab Socks V. D.—Case histories of venereal patients printed week-by-week in a Columbus tabloid increased the paper's circulation satisfactorily and brought in plenty of customers for the rapid treatment center. The newspaper received a thousand requests for "literature."

FREEBLE, C. R., and ROBINSON, A. The Tabloid Newspaper as a Medium of Mass Public Venereal Disease Education. J. Ven. Dis. Inform. 29, 10:307 (Oct.), 1948.

Thought for the Month—It is not only the individual who can be perverted by information beyond his capability of absorption; the community, too, can react in a bizarre manner to an instinctive urge or some new fashion of thought. History abounds, the writer comments, in examples of psychic contagion. Isn't "psychic contagion" a nice phrase?

GRANT, J. The Stigma—A Problem of Social Medicine. J. Roy. San. Inst. 68, 6:593 (Nov.), 1948.

"Tribute to the Machine Age"—If you'd like a good, comfortable chuckle, hunt out this short item written by a witty sanitarian. Incidentally it will set you to wondering, a bit *un*comfortably, about the possibilities of such contraptions (see title below) in your own bailiwick.

HERRIN, W. J., JR. A Sanitarian Views a Doughnut Machine. The Sanitarian. 11, 2:58 (Sept.-Oct.), 1948.

Inverse—Over a twenty year span between community health surveys, the relationships of economic status and chronic disease were looked into. Families going downhill economically had

twice the illness rate of those families whose fortunes were looking up. Which was cause and which was effect are discussed.

LAWRENCE, P. S. Chronic Illness and Socio-Economic Status. Pub. Health Rep. 63, 47: 1507 (Nov. 19), 1948.

Wearying of Well-Doing — An effort to improve the nutrition of a group of Canadian school children through education of both parents and youngsters produced some results the first year, but "improvement in health was not continued during the second year and some deterioration was observed." Such honest reporting is as commendable as it is unusual.

SHAVER, E. M., *et al.* Nutritional Aspects of the Hartman Jones Memorial School Health Study. Canad. Pub. Health J. 39, 10:395 (Oct.), 1948.

New Knowledge: New Responsibilities—Though quarantine has been divested of much of the mumbo-jumbo which surrounded it, carefully supervised isolation procedures have lost none of their usefulness. If public health nurses are given more discretion now-a-days, they become all the more responsible. Better nursing is called for.

SHETLAND, M. Communicable Disease Nursing—1948. Pub. Health Nurs. 40, 11:543 (Nov.), 1948.

Target To Shoot at—Can you mold your words into bullets? This is the way Stokes does it. "Sex is now a physical property, like a car: a lure hung with furs, a smell with a suggestive name, something with a three-way stretch and seductive points—to be acquired, used, traded in for a newer model or rented for the occasion or the night like tie and tails." Read the whole paper.

STOKES, J. H. The Modern Venereal Disease Problem and Its Sex Education Front. J. Ven. Dis. Inform. 29, 10:296 (Oct.), 1948.

Why TB Patients Leave—In this discussion of measures to reduce the large numbers of patients who leave V A tuberculosis hospitals against advice, the word "health educator" does not seem to figure prominently. Better doctor-patient relationships are called for, and so are better social services to solve patients' problems. Health educators will suggest that they have a contribution to make to this worthy cause.

TOLLEN, W. B. Irregular Discharge. Pub. Health Rep. 63, 45:1441 (Nov. 5), 1948.

. . . And the Poor Get Sicker—Some of the breadth, and a lot of the limitations, of our understanding of the influences of social and environmental factors upon our national health are revealed in these four excellent researches into variations in morbidity and mortality rates.

WIEHL, D. G. Mortality and Socio-Environmental Factors, (and) DOWNES, J. Social and Environmental Factors in Illness, (and) BRITTEN, R. H. Physical Impairments and Socio-Environmental Factors, (and) COLLINS, S. D. Sickness Among Industrial Employees in Baltimore in Relation to Weekly Hours of Work, 1941–1943. Milbank Quart. 26, 4:335 (Oct.), 1948.

Pollyanna, Pass This By—Grim is the word for the chance of survival into middle age for children with rheumatic fever. Only half live beyond age 40. The likelihood of the affected child to reach each of the decade markers up to 40 are worked out with unrelenting mathematical exactitude.

WILSON, M. G., and LUBSCHEZ, R. Longevity in Rheumatic Fever. J.A.M.A. 138, 11:794 (Nov. 13), 1948.

Lighting Up the Great Darkness—Federal funds to the tune of 14 millions, many more millions of state appropriations, "Substantial aid" from the A. C. S. are ear-marked for cancer control—but more is needed if the disease is to be stopped. Above all there must be unification of effort, says this writer.

ZIMAND, S. Public Health Aspects of Cancer Control. Milbank Quart. 26, 4:430 (Oct.), 1948.

Public Health in Foreign Periodicals

GEORGE ROSEN, M.D., PH.D.

OBSERVATION of current medical and public health literature from Latin American countries clearly reveals the considerable efforts that are being made to deal with problems of health. Demographic questions, infant mortality, tuberculosis, malaria, venereal disease, nutrition, parasitic infestations —all are being studied and are receiving attention. In different countries these tendencies are evident in greater or lesser degree. Brazil affords an interesting illustration in point.

BRAZILIAN DEMOGRAPHY AND VITAL STATISTICS

Like the United States and other countries of the Americas, Brazil passed through a colonial stage, the influence of which is still evident. The meaning of the colonial period has been clearly presented in two works that are indispensable for an understanding of Brazilian development. These are *Casa-Grande & Senzala* by Gilberto Freyre[1] and *Os Sertões* by Euclides da Cunha.[2] Both authors lay emphasis on the heterogeneity of the Brazilian population, and indicate the role of immigration in forming the Brazilian of today. The significance of migration in the growth of Brazil's population is studied in detail in a recent monograph by Giorgio Mortara.[3] At the very outset,

Mortara points out that demographic studies of American populations have been considerably handicapped by deficiencies of birth and death registration, and by the absence or irregularity of population censuses in many countries of the Western Hemisphere. Even in the United States where censuses have been taken since 1790, the registration of births and deaths has attained a satisfactory degree of completeness only very recently. In other American countries, among them Brazil, this goal is still far off.[4] Nevertheless, skillful utilization of available statistical data permits a good approximation to the missing information, and thus a reconstruction of population development.

Mortara ascribes the total increase in American populations to two different growth factors, one, excess of immigration over emigration, and, two, excess of births over deaths. He then proceeds to study population growth in Brazil during the last hundred years, and presents a brief account of the five Brazilian population censuses (1872, 1890, 1900, 1920, 1940). From a comparative analysis of the results of these censuses it can be shown that there was some understatement of the total population in the 1900 census, and a relatively greater overstatement in the 1920 census.

A special problem in the interpretation and correction of census data is considered in a critical analysis of the declarations of old age, particularly of declarations by centenarians. Ignorance, amnesia, and senile vanity all tend to raise declarations of extremely advanced age to almost incredible proportions. In countries where birth registration is long established and well organized, such errors are not so frequent and can be corrected by comparison of declared ages with information in birth registers. However, where such information is lacking, as in Brazil, control is virtually an impossibility. By comparative analysis and by applying survival rates calculated from Brazilian life tables, Mortara determined approximately the true number of centenarians in 1940. Comparison of this estimate with the data obtained in the 1940 census showed that untrue declarations of extremely advanced age were still frequent, although relatively less than in earlier censuses.

Brazilian public health authorities are aware of the deficiencies in their vital statistics. Provisional data in a survey undertaken by the Federal Biostatistics Service show that in 1945 the percentages of non-registered live births ranged from 64.7 (Teresina) to 21.6 (Curitiba).[5] Similarly, deaths are not completely registered. In 1943, 1944, and 1945 respectively, 1.8 per cent, 1.46 per cent, and 1.4 per cent of deaths reported to the Federal Biostatistics Service were not recorded by the registrars. Far worse, however, is the situation regarding stillbirths (and abortions), of which 68 per cent, 67.2 per cent, and 63.3 per cent known in the Federal District in 1943, 1944, and 1945 respectively were not registered.

In order to obtain more complete reporting the Serviço Especial de Saúde Pública decided to carry out a systematic investigation in areas which it covers in the Amazon and Rio Doce regions. For live births additional information is to be collected from baptisms and similar religious acts, as well as from maternity institutions, visiting nurses, child hygiene service, dispensaries and home immunizations. Additional information on deaths and stillbirths is to be supplemented by data from other sources, especially cemeteries serving the area under control.

WATER SUPPLY IN VARIOUS REGIONS OF BRAZIL

The problem of water supply and sewerage is also of considerable concern to Brazilian public health workers.

Gonçalves Ferreira points out that the installation of good water supply and sewerage systems is of primary importance in improving the health and well-being of the people of Brazil.[6] Statistics show that installing such services, as well as other public health measures, in Brazilian cities can save annually the lives of 15,000 people who now die of typhoid fever, dysentery and other enteric diseases. Examination of typhoid fever death rates in the Federal District for the last two 5 year periods reveals sanitary conditions that are not flattering to the capital of Brazil. The sewerage system is still poor, with over 50 per cent of the houses not connected to the system, and without privies of any kind. Furthermore, the water supply system is also not without defects. In considerable degree, unsatisfactory health conditions in Rio de Janeiro, of which frequent outbreaks of typhoid fever offer eloquent testimony, are due to the factors described.

Ferreira goes on to say that water cannot be considered of good quality, even though obtained from well protected springs, if it does not undergo any treatment. In the Rio Doce Valley, where water from the subsoil is generally unsuited for drinking purposes unless treated, the cost of treatment, including filtration system and reservoirs, has been calculated at Cr $250 per capita for the entire system. In the Amazon Valley the Serviço Especial de Saúde Pública has successfully shown that dug wells of large diameter are good, practical, and economical sources of drinking water for the majority of the urban communities in that area. It has been estimated that complete cost of installation, including wells, elevated reservoir, and distribution system, would be Cr $100 per person..

To remedy existing conditions, Ferreira proposes that every state in Brazil, including the Federal District, should have a Division of Sanitary Engineering in the Public Health Department. This division should be responsible for studying, supervising, and giving advice on water purification, sewage treatment, garbage disposal, insect and rodent control, food sanitation, disposal of industrial wastes, and sanitation of swimming pools.

In part, projects of this kind are being carried out in various parts of Brazil. These are connected with a water supply study recently undertaken by the Sanitary Engineering Section of the National Department of Health. This study envisages two stages. The first phase, which is now being carried out, is concerned with ascertaining the water needs of the Brazilian population, and the relations of these needs to financial resources in the different localities. The second phase, revolves around the assembling of data for the solution of specific problems. A full discussion of this water supply study as well as of other sanitary engineering activities in Brazil is available in a recent paper by Carvalho.[7] Other reports that may be consulted in this connection are those by Bovée,[8] Hummel,[9] and Miranda and coworkers.[10]

SCHISTOSOMA MANSONI IN BRAZIL

Among the public health and medical problems of Brazil those arising out of parasitic infestation occupy a prominent place. In a recently published monograph, Meira draws particular attention to one of these, schistosomiasis due to *S. mansoni*.[11] The author considers schistosomiasis an important public health problem and emphasizes its social, economic, and medical significance. Review of the available data indicates that published surveys do not give a true picture of the extent of the infection. There is substantial evidence that schistosomiasis mansoni is intensely endemic in extensive areas of Brazil. Surveys have been conducted by means of stool examinations, as well as through

pathological examinations, including liver biopsies. The incidence has been estimated at 6.2 per cent for the country as a whole. This figure would correspond to 2,808,600 individuals with schistosomiasis. For the Northern States and Minas Gerais only, which are known to be important endemic foci, Meira found the incidence to be 8.65 per cent and estimated that the approximate number of infected people was 1,817,892 in that area. He regards the true prevalence as exceeding these figures.

As regards the prevalence of schistosomiasis, Sergipe and Alagoas occupy first and second place, while the states of Bahia, Pernambuco, and Minas Gerais are third, fourth and fifth respectively. Infection with *S. mansoni* is known to occur all over Brazil, but except for a few areas the data are fragmentary and unrepresentative. Finally, Meira emphasizes the incomplete knowledge concerning the geographical distribution of the intermediate hosts of *S. mansoni*. For all those interested in this subject, this monograph has a bibliography which includes almost all the papers published in Brazil on schistosomiasis.

TUBERCULOSIS IN BRAZIL

Another problem of considerable importance is tuberculosis. This problem is being attacked from various points of view. Considerable attention is being given to statistical variations in mortality. For example, Machado reports on the tuberculosis mortality in various municipalities of Rio Grande do Sul during the period 1941–1943.[12] He found that the rate for all forms of tuberculosis was 97 per 100,000 population. There were wide variations, however, ranging from 5 to 411 per 100,000.

In the same state (Rio Grande do Sul), Costa studied the tuberculosis death rate in relation to socio-economic conditions.[13] He compared three regions with different economic characters, one predominantly pastoral, the second characterized by small industry and agriculture, and the third area by agriculture and cattle raising. Comparison of the death rates for the three zones showed a high rate for the predominantly pastoral, frontier region as compared to the other two.

Neves points to the necessity for employing different techniques when carrying on mass surveys of urban and rural populations.[14] In the Latin American countries the tuberculosis problem has a dual aspect, rural and urban. Mass x-ray surveys are particularly indicated for urban working class populations over the age of 15. On the other hand tuberculin testing is important for rural inhabitants up to the age of 25, and among urban individuals from 12 to 15.

The significance of the tuberculosis problem in Brazil may be seen again from Cardoso's study of the disease in Aracaju, capital of Sergipe.[15] In this city tuberculosis has assumed epidemic aspects, and accounts for 10 per cent of the total mortality. The greatest mortality occurs in the 21 to 40 age group, and also in males. Domestic servants and workers provide the bulk of those who are attacked by the disease. Tuberculin testing of individuals in the 9 to 14 age group showed 52.2 per cent positive. Cardoso emphasizes that the tuberculosis control program must be based on the epidemiology of the disease, taking as its basis the triad: host, infecting organism, social environment. No control of tuberculosis is possible without some improvement of housing and nutrition.

De Paula and Santos report their experiences with tuberculosis in pregnancy.[16] During a 2 year period they treated 43 pregnant women with tuberculosis. After analysis of the obstetrical condition of each patient and the state

of the pulmonary disease, they reached the conclusion that the way to care for these patients was to treat the tuberculosis and to observe the pregnancy. De Paula and Santos advise chest x-ray surveys for pregnant women, establishment of separate maternity sections for pregnant women with tuberculosis, and BCG vaccination of the new-born babies. Finally, they feel that abortion is justified only in exceptional cases.

De Assis also recommends BCG vaccination for the prevention of tuberculosis among infants in Rio de Janeiro.[17] He points out the advantages of oral administration. After discussing the Brazilian work on BCG he arrives at the conclusion that BCG is responsible for a reduction of 50 per cent in tuberculosis morbidity, and of about 80 per cent in tuberculosis mortality. De Assis then discusses the problem of revaccination with his method, which consists in the oral administration of six monthly doses of 100 milligrams each of BCG. He presents the results of his experiences with 61 children, each one living with at least one tuberculous person. The incidence of primary infection in this group was 11.45 per cent, the mortality zero.

New Year's Message from the President of the American Public Health Association

I welcome this opportunity to extend warm and cordial greetings to those who are devoting their lives to public health service.

As 1949 opens it must be gratifying to you as it is to me to realize that the public is recognizing its dependence on the public health professions more than ever before. Undoubtedly this places upon you and me a heavier obligation than we have previously carried for doing the job well. I like to think of the new resources we have in trained persons, in expanded programs, and more adequate money. We shall not be found wanting throughout the months of this year.

A generation ago Hermann M. Biggs pointed out that "Public health is purchasable and, within certain limits, communities may determine their own death rates." That is an appealing challenge. We should help the public to accept the challenge, as a philosophy, and we must make sure that into that acceptance we are ready to put the organization and the personnel to achieve this happy end.

Such a philosophy puts a high premium on planning for the future so that the public may find us ready to meet our task, which is the promotion of health, the prevention of disease, and the prolongation of life.

The Association has recently had a visitor from Germany who came with the express purpose of finding what the American Public Health Association represented. He asked many discerning questions, underlying all of which was his query, "How does it come that in North America the public health professions have organized themselves under auspices that include all branches of the professions and which over a period of years have exerted a profound influence on all aspects of the public health movement?" It would be understandable, he said, if the American Public Health Association were vested with legal authority. How does it happen that without a scintilla of authority the Association has been able, for example, to publish the definitive report on communicable disease control for more than three decades, which has periodically been approved by the United States Public Health Service and more recently by other governments?

These questions have led some of us to look at the American Public Health Association from a fresh viewpoint. We are grateful for the privileges we have of serving the public through this voluntary association of ours, and we venture to hope that through 1949, as in future years, we may continue to be strong and free.

President

ASSOCIATION NEWS

ACTION ON PROPOSED AMENDMENTS TO CONSTITUTION AND BY-LAWS, A.P.H.A.

The A.P.H.A. membership will be interested in the vote on the Constitutional Amendments proposed by the Committee on Constitution and By-Laws with the approval of the Governing Council and the Executive Board and published in the October issue of the *American Journal of Public Health* (page 1473).

Proposed Constitution Amendments Nos. 1 and 2 provided for the election of the ten elective members of the Governing Council annually by the members and Fellows instead of by Fellows only. The affirmative action of two-thirds of the Fellows voting at the Annual Meeting was required for the adoption of these amendments. The affirmative votes totaled 292, lacking 7 votes of the 299 required for adoption. There were 95 negative votes and Constitution Amendments 1 and 2 were correspondingly not approved.

Constitution Amendment No. 3 clarified the terms of newly elected councilors which begin with the first meeting of the New Governing Council held immediately after the Old Governing Council adjourns. This Amendment was adopted with 383 affirmative votes and 4 negative votes.

Constitution Amendment No. 4 provided for a mail vote by Fellows on amendments to the Constitution instead of restricting this important responsibility to those Fellows present and voting at an Annual Meeting. This Amendment received 370 affirmative votes and 16 negative.

Amendments 3 and 4 were declared adopted and effective with the close of the 76th Annual Meeting on November 12, 1948.

Certain amendments to the A.P.H.A. By-Laws were proposed to members of the Governing Council by the Committee on Constitution and By-Laws in compliance with the requirement of prior notice before amendments may be considered. The entire Constitution and By-Laws will be reprinted in its revised form in a forthcoming issue but in the meantime a brief summary is presented of the Governing Council actions on the seven amendments proposed to the By-Laws.

By-Laws Amendment No. 1 was a simple clarification of the rights of Honorary Fellows who retain all the privileges of Fellowship or membership under their former status. It was unanimously adopted.

By-Laws Amendment No. 2 was planned to implement proposed amendments Nos. 1 and 2 of the Constitution if they were passed. Under the circumstances By-Laws Amendment No. 2 was withdrawn. It is not now part of the By-Laws.

By-Laws Amendment No. 3 liberalizes a former policy of canceling dues of persons who have been affiliated for a long period. This amendment, which was adopted, provides dues exemption for persons who have been affiliated for thirty years and who have been retired, and it covers the forty year arrangement which previously abolished dues after forty years regardless of retirement, but which has not been previously carried in the By-Laws.

By-Laws Amendment No. 4 was adopted as an entirely new article providing for the election of elective members of the Governing Council *by mail* by Fellows only, instead of the existing procedure whereby only Fellows attend-

ing the Annual Meeting might vote for the elective councilors. This amendment sets up the necessary steps for a mail ballot but makes no change in the method of selecting Governing Council nominees nor the composition of the Nominating Committee. It is provided, however, that the President shall appoint the Tellers in advance of the Annual Meeting.

By-Laws Amendment No. 5 provides three year terms for the three representatives from the Health Officers Section to the Committee on Administrative Practice. Previously these had been elected annually. It was adopted.

By-Laws Amendment No. 6 clarifies the responsibilities of the Standing Committee on Research and Standards. It was adopted and the Committee is now responsible for initiating, conducting, promoting, coördinating and reviewing research and development of standards in the technical branches of public health.

By-Laws Amendment No. 7 modifies the routine for fixing the time of the Annual Meeting, committing this responsibility to the Executive Board where as a matter of fact it has been exercised for many years. It was adopted.

New By-Laws became effective as of November 12, 1948.

RESOLUTIONS

THE following Resolutions were unanimously adopted by the Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948:

1. APPRECIATION TO OFFICIALS AND GROUPS

RESOLVED that the American Public Health Association expresses its grateful appreciation to the Boston Committee and the agencies represented thereon for their gracious hospitality, and be it further

RESOLVED that the warm thanks of officers and members be extended to John H. Cauley, M.D., Chairman of the Boston Committee and his colleagues on the Committee for their many courtesies, generous contributions of time and energy, and their efficiency in making provisions for this meeting and in the conduct thereof.

2. THANKS TO THE AUDITORIUM AND HOTELS

RESOLVED that the American Public Health Association expresses its appreciation to the Mechanics Building, the Statler Hotel, and all other Boston hotels that opened their doors to us for their valuable assistance in the conduct of the Seventy-sixth Annual Meeting.

3. APPRECIATION TO THE PRESS AND RADIO

RESOLVED that the American Public Health Association acknowledges its indebtedness to the press and radio, national, state, and local, for excellent service in carrying to the people of America the important events of the Seventy-sixth Annual Meeting.

4. APPRECIATION TO EXHIBITORS

RESOLVED that the American Public Health Association expresses its grateful appreciation to those who have presented at its Seventy-sixth Annual Meeting the excellent exhibits, both scientific and technical, which are of such great interest and value to the public health profession.

5. IN MEMORIAM

RESOLVED that it is with a sense of irreparable loss that the American Public Health Association records, since its last Annual Meeting, the death of 66 Fellows and members, whose names constitute a part of this resolution.

Deceased Members and Fellows of the AMERICAN PUBLIC HEALTH ASSOCIATION—October, 1947, through October, 1948

6. THANKS FOR SPECIAL PRIVILEGES EXTENDED

Of unusual interest and value to the participants at this Seventy-sixth Annual Meeting have been the many opportunities to see at first hand many of the scientific, industrial and historical features of the Boston area.

RESOLVED that the American Public Health Association expresses its sincere thanks to the agencies of the City of Boston and the State of Massachusetts, to the universities and hospitals of Greater Boston, and to those industrial organizations that made their services available for the special benefit of our members.

7. RESEARCH IN CHILD LIFE

WHEREAS, there is great need for exchange of information about studies in progress concerning physical, mental, social, and emotional problems of children, and

WHEREAS, at the request of research workers, a Clearing House for Research in Child Life is being established in the Children's Bureau, therefore be it

RESOLVED that the American Public Health Association respectfully directs the attention of public health workers to this clearing house and recommends their full support in promoting its activities and their participation in supplying information about research projects to the clearing house.

8. SCHOOL HEALTH

WHEREAS, the American Public Health Association is concerned with the health of the total community, and

WHEREAS, it has become increasingly clear that the school health program can contribute significantly to the overall public health program, and

WHEREAS, both education and health departments have great interest in the health of the school age child, and

WHEREAS, it is becoming increasingly apparent that where there is a high degree of mutual understanding and coöperation between departments of health and education, with the resultant pooling of the resources of both departments, good school health programs are being developed, be it

RESOLVED that the American Public Health Association join with the National Education Association and the American Medical Association and other groups in approving the principle of coöperative planning of health programs which involve children of school age.

9. HEALTH OF SCHOOL CHILDREN

WHEREAS, the allocation of the moneys to schools and school districts is based upon a variety of formulae, among which is the classroom unit as computed by average daily attendance, and

WHEREAS, if funds are allotted on the basis of average daily attendance,

school officials find it to their advantage strongly to promote daily attendance of all children at school, and

WHEREAS, the encouragement of children to attend school when they are ill has deleterious effects upon the health of individual children and may be responsible for the spread of communicable disease, therefore, be it

RESOLVED that the American Public Health Association join with the National Education Association, the American Medical Association and other groups in decrying this practice, and be it further

RESOLVED that the National Council of State School Officers and the Association of State and Territorial Health Officers be urged to develop a plan of allotting tax moneys for educational purposes in a way that is not deleterious to the health of children.

10. EDUCATION OF NURSES

WHEREAS, there has been a particularly significant study of the education of nurses conducted by Dr. Esther Lucile Brown at the request of the National Nursing Council and financed by the Carnegie Foundation, (*Nursing for the Future,* Esther Lucile Brown, Ph.D., published by the Russell Sage Foundation, 1948), and

WHEREAS, the findings of this study have far-reaching implications for the future education of nurses for public health, therefore be it

RESOLVED that the Committee on Professional Education of the American Public Health Association give the report its thoughtful consideration.

11. RECRUITMENT OF NURSES

WHEREAS, an acute shortage of nursing personnel still exists, and

WHEREAS, there is particular shortage of nurses with preparation for leadership responsibilities, and

WHEREAS, nursing in public health depends upon development of nursing leaders, and

WHEREAS, preparation for such leadership is best provided in the university schools of nursing and, since the facilities of these schools are not being completely utilized, therefore be it

RESOLVED that the American Public Health Association lend its support to the Joint Committee on Careers in Nursing of the National League of Nursing Education in recruitment of students for university schools of nursing.

12. 1950 BIRTH REGISTRATION TESTING

WHEREAS, birth records and the statistics developed from them are essential for the planning, operation and evaluation of local, state, and national health programs, and

WHEREAS, improvement in registration completeness would increase the usefulness of the birth records for the efficient operation of these programs, and

WHEREAS, the successful promotion of complete registration depends on a knowledge of the status of such completeness by urban-rural and other characteristics for local areas and states

RESOLVED that the American Public Health Association considers it essential that a uniform nation-wide test of birth registration completeness be carried out to make available measures of registration completeness on local, state, and national levels, and that provisions be made to secure improvements in registration completeness.

14. MARRIAGE AND DIVORCE STATISTICS

WHEREAS, the American Public Health Association recognizes the need for more adequate marriage and divorce statistics, to provide much needed information on many aspects of the

health and well-being of the family, community, state, and nation; and

WHEREAS, these vital statistics of marriages and divorces can most feasibly be developed through the same channels as have proved effective for vital statistics of births and deaths, as part of the public health programs of the several states, with development of national statistics through coöperative state-federal relationships; now therefore be it

RESOLVED, that the American Public Health Association expresses its support for state centralization of marriage and divorce records and statistics and their integration with other vital records and statistics, and urges all states not yet operating such an integrated system to effect this urgently needed change at the earliest possible time; and be it further

RESOLVED that the American Public Health Association calls upon the National Office of Vital Statistics in the Public Health Service of the Federal Security Agency to take all steps possible for encouraging the development of systems of marriage and divorce records and statistics in every state that will make for maximum uniformity, comparability, and prompt availability of data, and for developing a program of detailed national statistics of marriage and divorce, based on national registration areas for marriages and divorces, adequate to meet the pressing needs for such vital statistics.

15. FAMILY HEALTH PROGRAM

WHEREAS, there is evidence of lack of balanced service to families by public health agencies in the community, and

WHEREAS, this lack of balance is accentuated by the allocation of subsidy moneys and nursing time for special projects, be it

RECOMMENDED, that the American Public Health Association direct its Committee on Administrative Practice, in conjunction with the Public Health Nursing Section and any other Sections as would be affected, to give consideration to the problem of securing a more balanced family health program, and to report as promptly as possible to the Governing Council.

17. SCHOOL LUNCH PROGRAM

WHEREAS, the service of nourishing noon meals at school is an important part of a program of health services and health education for children of school age; and

WHEREAS, the benefits of school lunches are freely available to all children only where public funds defray a substantial part of the cost of food, service, and administration, and

WHEREAS, federal, state and local appropriations during recent years have not increased sufficiently to keep pace with rising costs of food and labor for preparing luncheons, therefore, be it

RESOLVED that the American Public Health Association hereby endorses increased federal support under the National School Lunch Act and adequate state appropriations for matching federal funds and for the efficient operation of the program.

18. SUPPORT OF HEALTH EDUCATION AND PUBLICITY HEADQUARTERS

WHEREAS, for many years the National Publicity Council has been performing a real service in health education through the maintenance of the Health Education and Publicity Headquarters at the Annual Meeting of the American Public Health Association, and

WHEREAS, the upsurge in interest in health education techniques, programs, and materials on the part of health workers other than health educators has increased the extent and comprehensive nature of the work the

National Publicity Council has done, and

WHEREAS, although the American Public Health Association has met part of the cost of maintenance of the Headquarters, the bulk of the cost of this increase in work has had to be absorbed from the operation budget of the National Publicity Council, and

WHEREAS, because of the enormous value of this service to all of those engaged in educational work in public health, it is desirable that the Health Education and Publicity Headquarters at the Annual Meeting of the American Public Health Association should be continued. Therefore be it

RESOLVED that the Executive Board make every effort that the American Public Health Association meet the full cost of the Health Education and Publicity Headquarters; and that the Health Education and Publicity Headquarters be an Association-wide activity.

20. RECRUITMENT OF PERSONNEL

WHEREAS, the nation now faces a serious situation because of the shortage of public health personnel in all fields, and

WHEREAS, it is anticipated that in the near future more programs of public health will be established even in the face of an admitted lack of personnel, be it

RESOLVED that the American Public Health Association plan and establish an intensive national program of recruitment of public health personnel in all fields coöperating with such other interested agencies as it is deemed necessary, and be it further

RESOLVED that the American Public Health Association seek sufficient funds from all available sources to place this recruitment program on a sound basis.

21. RECOGNITION OF INCREASED FEDERAL APPROPRIATIONS FOR PUBLIC HEALTH IN CANADA

WHEREAS, the health of the Canadian people is of direct interest and vital concern to this Association and to the people of the United States, and

WHEREAS, federal grants-in-aid in the United States have constituted a device of proven value in extending public health services and stimulating planned hospital construction, at the same time equalizing the financial burden nationally, and

WHEREAS, the Government of Canada has embarked on a generous and far-reaching program of grants-in-aid to the Provinces for health surveys, general public health purposes, tuberculosis control, mental health care, venereal disease control, crippled children, professional training, public health research, cancer control, and hospital construction, therefore be it

RESOLVED that the American Public Health Association extends its hearty congratulations to the government and people of Canada for a step which makes the year 1948 memorable in the annals of public health on this continent.

HEALTH OFFICERS — 1948 INVENTORY

Are you planning to use the *Evaluation Schedule* to measure progress in 1948? Copies of the *Schedule* and the Guide to its use will be sent free upon request.

For a detailed study of your community sanitation program, ask for the new *Sanitation Evaluation Schedule.*

COMMITTEE ON ADMINISTRATIVE PRACTICE
AMERICAN PUBLIC HEALTH ASSOCIATION

TELEGRAM TO DR. MARTHA M. ELIOT FROM PRESIDENT TRUMAN

"It is my great pleasure to congratulate you, Dr. Dyer, Dr. Dubos, Dr. Waksman, Dr. du Vigneaud, Dr. Hawley and Dr. Magnuson, this year's winners of the Lasker Awards, and to convey to all of you the gratitude of the Government and that of millions of Americans for outstanding contributions to the health of our people.

"The foundation of a strong and healthy democracy depends largely on the ability of modern medicine and research to marshal its resources and to place them at the service of all the people. You as a group and individually have helped to fill these needs. You have all made contributions which have saved lives of untold thousands. The fact that the average expectancy of life has been increased a little more than six years from 1936 through 1946 is an example of what research, organization, and dissemination of new knowledge and drugs can do, and of what can be done in the future. If we attack diseases of the heart and circulatory system and cancer, which now account for over 55 per cent of the annual deaths of our people, through more research and control measures, new strides in human well-being will be made.

HARRY S. TRUMAN"

November 11, 1948

A.P.H.A. CREATES NEW SECTION ON MEDICAL CARE

A new section on Medical Care of the American Public Health Association was established by the Governing Council at the Annual Meeting in Boston on November 10. This Section will provide a medium for exchange of experience with respect to program content, administration, and technical aspects of the various fields of medical care, such as voluntary and public medical care plans, hospital services, group practice, chronic disease, and rehabilitation.

The officers of this section are:

Chairman—Edward S. Rogers, M.D., Dean, School of Public Health, University of California

Vice-Chairman—Edwin L. Crosby, M.D., Director, Johns Hopkins Hospital

Secretary—Milton Terris, M.D., Medical Associate, Subcommittee on Medical Care, A.P.H.A.

The members of the Section Council are: Dean A. Clark, M.D., Medical Director, Health Insurance Plan of Greater New York; Edwin F. Daily, M.D., Director, Division of Health Services, Children's Bureau; Herbert L. Lombard, M.D., Director, Division of Cancer and Other Chronic Diseases, Massachusetts State Department of Public Health; Ellen C. Potter, M.D., Deputy Commissioner for Welfare, New Jersey State Department of Institutions and Agencies; and Marian G. Randall, R.N., Executive Director, Visiting Nursing Service of New York.

GOVERNING COUNCIL ELECTS THREE HONORARY FELLOWS AT BOSTON

The governing Council of the American Public Health Association, on recommendation of the Committee on Eligibility, unanimously elected three Honorary Fellows at the Annual Session in Boston on November 10, 1948.

Brock Chisholm, M.D., Director General. World Health Organization, Geneva, Switzerland

V. Mary Crosse, O.B.E., M.D., Specialist in Prematurity of the City of Birmingham Department of Health, England

Karl Evang, M.D., Surgeon General of the Norwegian Public Health Service, Oslo. Norway

This brings to a total of 23 the Honorary Fellows elected to the American Public Health Association. These persons are distinguished public health workers who, with rare exceptions, live outside of North America.

The twenty Honorary Fellows elected in previous years are shown below with

the year each was added to the Honorary Fellowship roster.

George F. Buchan, M.D., London, England 1928
Hugh S. Cumming, M.D., Washington, D. C. 1936
Kendall Emerson, M.D., New York, N. Y. 1935
James Fenton, M.D., London, England 1931
Raymond E. Fosdick, LL.D., New York, N. Y. 1946
William M. Frazer, M.D., Liverpool, England 1942
Herbert C. Hoover, Palo Alto, Calif. 1923
William W. Jameson, M.D., London, England 1933
Thorvald Madsen, M.D., Copenhagen, Denmark 1926
Arthur Massey, M.D., Coventry, England 1944
E. R. A. Merewether, M.D., London, England 1942
Sir George Newman, London, England 1931
Sir John Boyd Orr, Aberdeenshire, Scotland 1942
Robert Hughes Parry, M.D., Bristol, England 1943
Gustavo Pittaluga, M.D., Havana, Cuba 1935
Charles Porter, M.D., London, England 1931
Sir Allan Powell, London, England 1931
Florence R. Sabin, M.D., Denver, Colo. 1947
René Sand, M.D., Brussels, Belgium 1946
Andrisa Stampar, M.D., Zagreb, Yugoslavia 1946

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Malcolm A. Bouton, M.D., M.P.H., 2039 Baker Ave., Schenectady, N. Y., Commissioner of Health
Guy G. Campbell, M.D., 232 Zamora Ave., Coral Gables, Fla., Recently Director General of Public Health for Ethiopia
Ricardo Cappeletti, M.D., Ministerio de Salud Publica, Montevideo, Uruguay, Director, Division of Hygiene
Elizabeth P. Fleming, M.D., 19 Wallis St, Beverly, Mass., Surgeon (R) (Ret.), U. S. Public Health Service
William V. Garnier, M.D., 203 Civil Courts Bldg., New Orleans, La., State Health Officer and President, State Board of Health
David D. Helm, V.M.D., Health Department, City Hall, Camden, N. J., Health Officer and Registrar of Vital Statistics
Theodore F. Hilbish, M.D., M.P.H., 5809 Chillum Gate Road, Hyattsville, Md., Asst. Chief, Tuberculosis Control Division, U. S. Public Health Service
Miles F. Kelly, M.D., 216 West 4th St., North Little Rock, Ark., Medical Director, North Little Rock City Health Dept.
Thaddeus D. Labecki, M.B., Box 310, Indianola, Miss., Director, Sunflower County Health Dept.
Charles-Henri Laurin, M.D., D.P.H., Immigration Detention Hospital, West Quebec, Que., Canada, Chief Administrative Medical Officer
Frederic F. Maloof, M.D., 178 Huntington Ave., Boston 15, Mass., Medical Inspector, Boston Health Dept.
George A. Miners, M.D., Box 308, Bemidji, Minn., Medical Director, District Health Unit 1
John S. Moorhead, M.D., M.P.H., Commissioner of Health, Charlotte Amalie, Virgin Islands
Eugene E. Taylor, M.D., Box 55, Mocksville, N. C., Health Officer, Davie-Stokes-Yadkin District Health Dept.
Roy J. Ward, M.D., 9 Bellevue St., Worcester, Mass., Epidemiologist, Worcester Health Dept.

Laboratory Section

Samuel R. Bozeman, Ph.D., State Department of Health, Lansing, Mich., Asst. Director, Biologic Products Division, Bureau of Laboratories
Ann S. Buck, A.M., 310 Beacon, Boston 16, Mass., Research Bacteriologist, Harvard Medical School
James W. Farrell, 19 Prospect St., Summit, N. J., Senior Technician, Fair Oaks Sanatorium
Marion Hood, D.Sc., Dept. of Pathology, Charity Hospital, New Orleans 12, La., Microbiologist
Jack Kasten, 2671-30th St., Long Island City, N. Y., Laboratory Asst., New York City Health Dept.
Wilfred C. Kennell, 2352 Augusta Ave., Fresno, Calif., Chief Public Health Technician, Fresno County Dept. of Public Health
Norman D. Levine, Ph.D., Coll. of Vet. Med., Univ. of Illinois, Urbana, Ill., Assoc. Professor and Asst. to Dean, Dept. of Veterinary Pathology and Hygiene
John P. Newman, D.V.M., Dept. of Bact.,

Michigan State College, East Lansing, Mich., Asst. Professor of Bacteriology

Carlos Quiros, M.D., 68 High St., Brookline, Mass., Student, Harvard School of Public Health

Lillian Robbins, M.S., 224 East 27 St., New York 16, N. Y., Senior Bacteriologist, Bellevue Hospital

Harry Schwachman, M.D., Children's Medical Center, Boston, Mass., Director, Clinical Laboratory

Victor N. Tompkins, M.D., Div. of Labs. & Research, State Health Dept., Albany, N. Y., Acting Asst. Director

Henry Turkel, M.D., M.A., 650 W. Boston Blvd., Detroit 2, Mich., Private Practice and Consultant on Bone Marrow Infusions

Catherine J. Witton, M.A., 300 The Fenway, Boston 15, Mass., Assoc. Professor of Biology, Simmons College

Statistics Section

Anita Bahn, 8808 Manchester Rd., Silver Spring, Md., Biostatistician, U. S. Public Health Service

Edith A. Hulshouser, Kapiolani Maternity Hospital, 1611 Bingham St., Honolulu, T. H., Medical Record Librarian

Robert Kohn, D.J., M.A., Dominion Bureau of Statistics, Ottawa, Ont., Canada, Statistician, Health and Welfare Section

William I. Lourie, Jr., M.P.H., 5500 Johnson Ave., Bethesda 14, Md., Biostatistician, U. S. Public Health Service

Mary Nunez, R.R.L., Memorial Hospital, Pawtucket, R. I., Chief Medical Records Librarian

Anthony E. Wilby, Provincial Dept. of Health, Parliament Bldgs., Fredericton, N. B., Canada, Asst. Registrar General

Roland E. Zook, M.P.H., 1606½ South Sixth St., Springfield, Ill., Special Research Analyst, Division of Services for Crippled Children, Univ. of Illinois

Engineering Section

L. T. Barnard, 200 S. Colorado, Midland, Tex., Senior Sanitarian, Midland, Ector and Howard County Health Unit

Reece Cantrell, 921 Commonwealth Ave., Waukegan, Ill., Junior Chemist, Abbott Laboratories

Donald D. Gold, Hydraulics Lab., Univ. of Florida, Gainesville, Fla., Research Asst. and Graduate Student

Louis H. Herschler, Board of Water Supply, Honolulu 1, T. H., Sanitary Engineer

Theodore A. Kolb, M.S., 1006 Woodlawn Ave., Columbia, S. C., Senior Sanitary Engineer, State Board of Health

Edward C. LaValley, M.C.E., Masonic Temple Bldg., Ithaca, N. Y., Director of Environmental Sanitation, Tompkins County Health Dept.

Edward W. Moore, A.M., 112 Pierce Hall, Harvard Univ., Cambridge 38, Mass., Assoc. Professor of Sanitary Chemistry, Harvard Graduate School of Engineering

Willard J. West, 488 Brookside Drive, Springville, Utah, District Sanitarian, Health District IV

Industrial Hygiene Section

Major Joseph R. Arsenault, 3530 Atwater Ave., Montreal, Que., Canada, Public Health Officer, Canadian Army

Raymond E. Masters, M.D., 1144 Broadway, East McKeesport, Pa., Physician, Westinghouse Electric Corporation

Jack C. Radcliffe, M.S., 411 Fort Dearborn Ave., Dearborn, Mich., Supervisor, Industrial Health Unit, Medical Section, Ford Motor Co.

Arthur J. Vorwald, M.D., Ph.D., 7 Church St., Saranac Lake, N. Y., Director, The Edward L. Trudeau Foundation

Food and Nutrition Section

Florence V. Cavanagh, 745 Massachusetts Ave., Boston 18, Mass., Dietitian, Boston City Hospital, South Dept.

Pablo Liendo-Coll, M.D., 33-20 72nd St., Jackson Heights, N. Y., Chief Physician, Nutrition Dept., Instituto Nacional Administracion

Chester A. Newhall, M.D., 72 Colchester Ave., Burlington, Vt., Assoc. Professor and Chairman, Department of Anatomy

Eduardo Paez-Pumar, Jr., M.D., Calle Chapellin Qtz. Masparro, La Florida, Caracas, Venezuela, S. A., Instructor, Universidad Central de Venezuela

Maternal and Child Health Section

Harriett M. Bartlett, 988 Memorial Drive, Cambridge 38, Mass., Assoc. Professor, School of Social Work, Simmons College

Genevieve A. Grotz, M.D., Wayne County Health Dept., Henry Ruff Rd., Eloise, Mich., Director of Maternal and Child Health

Henry G. Mello, M.D., Harvard School of Public Health, Boston, Mass., Student

Marian C. Putnam, M.D., 244 Townsend St., Roxbury, Mass., Co-Director, The James Jackson Putnam Children's Center

Constantine R. Roscoe, M.D., M.S., 1930 Chestnut St., Philadelphia 3, Pa., Medical Inspector and Pediatrician, Philadelphia Dept. of Public Health

Albert R. Taylor, M.D., M.P.H., State Department of Public Health, State Capitol, Cheyenne, Wyo., Director, Division of Maternal and Child Health and Crippled Children

Public Health Education Section

Curtis E. Avery, M.A., Rm. 508, Education Center Bldg., 220 S. W. Alder, Portland, Ore., Director, E. C. Brown Trust

Roy E. Dickerson, LL.M., 312 West 9th St., Cincinnati, Ohio, Exec. Secy., Cincinnati Social Hygiene Society

Robert D. Feild, Newcomb College, New Orleans, La., Director, Newcomb Art School

Blanche L. George, International House, 500 Riverside Dr., New York, N. Y., Student, Columbia School of Public Health

Sidney S. Goosen, 3105 Carpenter, Detroit 12, Mich., Administrator, North Detroit General Hospital

Marguerite E. Green, M.P.H., 11 Waverly, Brookline, Mass., Health Educator, U. S. Public Health Service

Tin An Hu, M.D., c/o Dr. Loh, 103 Townsend St., Roxbury, Mass., President, National Kiangsu Medical College (China)

Andie L. Knutson, Ph.D., Office of Health Education, U.S.P.H.S., Washington, D. C., Chief, Research and Evaluation Section

Mary Jo Kraft, Tuberculosis Control Div., U.S.P.H.S., Washington 25, D. C., Health Educator

B. G. Loveless, Court House, Dallas, Tex., Health Educator, Dallas County Health Dept.

Fidel A. Maciel-Crespo, M.D., Calle 47-316, LaPlata, Argentina, S. A., Professor, Facultad de Medicina de La Plata

James C. McCullough, Rm. 605, 600 W. 168th St., New York, N. Y., Research Asst., Columbia University

Sheldon A. Miller, M.H.A., 2404 Callow Ave., Baltimore 17, Md., Hospital Division, U. S. Public Health Service

Merwin L. Noble, M.P.H., 3200 Humphrey Ave., Richmond, Calif., Health Educator, Richmond Health Dept.

Ivan B. O'Lane, M.P.H., 4417 Williams Ave., Seattle 99, Wash., Recently completed studies at University of Michigan School of Public Health

Katherine M. Olmsted, R.N., 832 James St., Syracuse, N. Y., Field Instructor, Division of Public Health Education, State Dept. of Health

Robert H. Pansky, R.N., Health Dept., 740 Main St., East Hartford, Conn., Health Inspector

Ann B. Tipton, M.A., 511 West 113th St., New York, N. Y., Instructor, Dept. of Physiology, Hunter College

Margaret Warner, M.P.H., 21 Searle Ave., Brookline, Mass., Health Educator, U. S. Public Health Service

Public Health Nursing Section

Eleanor Belfint, 823 West St., Wilmington, Del., Nursing Supervisor, State Board of Health

Ruth Bunker, R.N., 1715 Washington St., Charleston, W. Va., Nurse Consultant, Bureau of Tuberculosis Control, State Dept. of Health

Adele Henderson, R.N., 4550 Connecticut, N. W., Washington, D. C., Nurse, Prince George County Mental Health Clinic

Marcetta Horne, R.N., Box 330, Pittsfield, Mass.

Norma C. Larson, 74 Bruce Road, Waltham, Mass., Public Health Nursing Instructor, Massachusetts General Hospital School of Nursing

Pansy V. Murphy, 1851 Columbia Road, N. W., Washington, D. C., Senior Asst. Nurse Officer (R), U. S. Public Health Service

Gladys E. Warren, 604 City Hall, Spokane, Wash., Supervisor of Public Health Nursing, Spokane Visiting Nurse Assn.

Epidemiology Section

Fabio de Carvalho-Nunes, M.D., Travessa Bocanera Junior 6 Barris, Salvador, Bahia, Brazil, S. A., Physician, Division of Tuberculosis, Bahia State Health Dept.

Kenneth S. Young, D.V.M., State Health Department, Austin, Tex., Veterinarian, U. S. Public Health Service

Olga B. Furth, M.D., 1214 North Clinton, Dallas, Tex., Acting Director, School Health Service, Dallas Independent School District

Roy E. Joyce, M.S., 919 Whites Road, Kalamazoo, Mich., Asst. Professor of Biology and Hygiene, Western Michigan College

Howard S. Parsons, M.Ed., 309 Delaware Ave., McDaniel Crest, Wilmington 284, Dela., Director of Health and Physical Education, Mt. Pleasant Special School District

Floyd O. Reed, M.D., 27 Ludlow Street, Yonkers, N. Y., Acting Director, School Health Service, Board of Education

Dental Health Section

Harry K. Brown, D.D.S., D.D.P.H., 72 Metcalf St., Ottawa, Ont., Canada, Chief, Dental Health Division, Dept. of National Health and Welfare

Herbert L. Hayward, D.D.S., 72-A Fifth Walk, Brooklyn 12, N. Y., Private Dental

Practice and Fellow, New York University
James H. Pence, D.D.S., State Department of Health, Bismarck, N. D., Director, Division of Oral Hygiene
Naomie Turner, Ed.M., Forsyth Dental Infirmary, Boston, Mass., Research Assoc.

Medical Care Section

Mark A. Freedman, M.D., Bronx Hospital, 1276 Fulton Ave., New York 56, N. Y., Asst. Director
Anna Harrison, M.A., 2917 Ursuline Ave., New Orleans, La., Chief, Section of Medical Social Service, State Dept. of Health
Percy H. Jennings, Jr., M.D., 2580 Bancroft Way, Berkeley 4, Calif., Practising Pediatrician, Berkeley Pediatric Group
Mary A. Johnson, M.A., 600 West 168th St., New York, N. Y., Research Assoc. (Hospital Administration), Columbia Univ. School of Public Health
John P. Peters, M.D., 789 Howard Ave., New Haven 11, Conn., John Slade Ely Professor of Medicine, Yale Univ. School of Medicine
Stanley H. Saunders, 31 Canal Street, Providence, R. I., Exec. Director, Hospital Service Corporation of Rhode Island

Unaffiliated

Marcella Bernstein, 8010 Eastern Drive, Silver Spring, Md., Editor, Scientific Publications. Tuberculosis Control Division, U. S. Public Health Service
Franklin B. Caffee, U.S.P.H.S., 15 Pine St., New York 5, N. Y., Public Health Representative
Victor E. Costanzo, M.H.A., 1438 S. Grand, St. Louis 4, Mo., Instructor in Hospital Administration, St. Louis Univ.
Lawrence H. Flett, National Aniline Div., Allied Chem. & Dye Corp., 40 Rector St., New York 6, N. Y., Director, New Products Division
Henry M. Hardwicke, M.D., 180 N. Snelling, St. Paul, Minn., Medical Director, Health Center Services Committee
Paul R. Hawley, M.D., Dr.P.H., Associated Medical Care Plans, 330 S. Wells, Chicago 6, Ill., Chief Exec. Officer, Blue Cross and Blue Shield Commissions
Edward B. Holley, M.D., 1020 Boston Bldg., Salt Lake City, Utah, Practice of Pediatrics
O. H. Jacobson, D.V.M., 239 W. 13th South, Salt Lake City, Utah, Chief Veterinarian, Salt Lake City Health Dept.
Samuel S. Keener, M.D., 1203 Beacon St, Brookline, Mass., Private Practice
H. Clifford Loos. M.D., 947 West 8th St., Los Angeles 14, Calif., Administrator, Ross-Loos Medical Group

Lions Club in A.P.H.A.

At the 76th Annual Meeting of the American Public Health Association in Boston, a Lions Club from the membership of the A.P.H.A. was organized. The Chairman selected was Leonard C. Murray, Director of Health Education, Iowa State Health Department. It is planned that this group will meet each year in connection with the Association's Annual Meeting. Lions in the Association are reported by its Chairman to number about 60.

A.P.H.A. membership application blank on page XXXIII

EMPLOYMENT SERVICE

The following pages present information for those seeking qualified public health personnel and for those seeking positions in public health.

This is a service of the Association conducted without expense to the employer or employee.

Address all correspondence to the Employment Service, A.P.H.A., 1790 Broadway, New York 19, N. Y., unless otherwise specified.

POSITIONS AVAILABLE

Dentist-public health for new program in urban and rural communities served by County Health Department. Experience and graduate training in public health desirable. Salary $6,600 to $8,172. Write: Health Officer, Alameda County Health Department, San Leandro, Calif.

Public Health Physician, age 40, seeks appointment with Student Health or Health Department. Experienced and trained in all phases of public health work. Excellent references. South preferred. Will consider foreign appointment. Personal interview can be arranged. Give salary and particulars. Write Box Ph-10, Employment Service, A.P.H.A.

OPPORTUNITIES

Kentucky needs public health workers. There are vacancies for doctors, nurses, and other personnel both in the State Health Department and in County Health Departments. Salaries are open, depending upon qualifications. Write: Bruce Underwood, M.D., State Health Commissioner, Kentucky State Department of Health, 620 South Third Street, Louisville 2, Ky.

ANNOUNCEMENT OF POSTGRADUATE FELLOWSHIPS

Research

Research fellowships are available in Virology, Orthopedic Surgery, Pediatrics, Epidemiology, and Neurology. These fellowships are intended to emphasize: (1) advanced training in the basic sciences as they apply to the particular specialty and to research, and (2) experience in research, which need not be immediately related to poliomyelitis.

Eligibility requirements: M.D. (or when appropriate, a degree of Ph.D.); a minimum of two years of training on the residency level in the specialized field; presentation of an appropriate program of study and investigation; United States citizenship; sound health as attested by a physical examination.

Physical Medicine

Clinical fellowships are available to physicians who wish to prepare for eligibility for certification by the American Board of Physical Medicine.

Eligibility requirements: Graduation from a Class A school of medicine; completion of a rotating internship of not less than one year in a hospital approved by the Council on Medical Education and Hospitals of the A.M.A.; license to practise medicine in one or more states; citizenship in the United States; sound health as attested by a physical examination; age limit: 40.

Public Health

Fellowships are available to physicians for one year of postgraduate study leading to a Master of Public Health degree at a school of public health approved by the American Public Health Association.

Eligibility requirements: Graduation from a Class A school of medicine; completion of an internship of not less than one year in a hospital approved by the Council on Medical Education and Hospitals of the A.M.A.; license to practise medicine in one or more states; citizenship in the United States; sound health as attested by a physical examination.

Application may be made to the National Foundation for Infantile Paralysis, 120 Broadway, New York 5, N. Y., at any time during the year. Selection of candidates will be made on a competitive basis by committees composed of specialists in each field. Awards are based on the individual need of each applicant.

Announcement of Regular Corps Examination for Dietitians

United States Public Health Service

A competitive examination for appointment of dietitian officers in the Regular Corps of the U. S. Public Health Service will be held on February 28, 1949, at various points in the United States.

Appointments are permanent in nature and provide opportunities for a lifetime career in the field of dietetics at Marine Hospitals and other Public Health Service facilities.

Appointments will be made in the grades of Junior Assistant (2nd Lt.), Assistant (1st Lt.), and Senior Assistant Dietitian (Captain). Annual entrance pay is from $2,955.50 to $4,489.00 as determined by the grade of appointment and existence of dependents. All applicants must be graduates from an approved college and have a baccalaureate degree in the field of dietetics.

Additional information and application forms may be obtained by writing to:
Surgeon General, U. S. Public Health Service, Washington 25, D. C.
Attention: Division of Commissioned Officers.

Regular Corps Examination for Nurse Officers

United States Public Health Service

A competitive examination for appointment of nurse officers in the Regular Corps of the U. S. Public Health Service will be held on March 17, 1949, at various points in the United States.

Appointments are permanent in nature and provide opportunities for a lifetime career in the fields of clinical and public health nursing at Marine Hospitals, and in a variety of public health program.

Appointments will be made in the grades of Junior Assistant (2nd Lt.), Assistant (1st Lt.), and Senior Assistant Nurse Officer (Captain). Annual entrance pay is from $2,955.50 to $4,489.00 as determined by the grade of appointment and existence of dependents. All applicants must be registered nurses with a baccalaureate degree from an approved school of nursing. (Past nursing experience in the Army, Navy, or Public Health Service may serve, in certain instances, in lieu of academic degree.)

Additional information and applicaton forms may be obtained by writing to:
Surgeon General, U. S. Public Health Service, Washington 25, D. C.
Attention: Division of Commissioned Officers

Dentist; six years, military service; since receiving discharge on temporary appointment; 12 years, private practice during which time he served as public health dentist on part-time basis; before entering military service, several years' teaching experience; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Sanitary chemist; Ph.D.; four years, assistant professor of biology, midwestern college; past five years, consultant chemist, midwestern city where his duties include research in water and sewerage treatment; simultaneously has been holding important teaching appointment; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Public health nurse; Master's degree, major in public health supervision; six years, staff nursing, rural and city health departments; six years, supervisor, municipal department of health; seeks administrative position in education, tuberculosis, or public health nursing; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

NEWS FROM THE FIELD

Stone Heads National Advisory Committee on Local Health Units

Officers for the year 1949 were elected by the National Advisory Committee on Local Health Units at a meeting in New York on December 2. Thus, a committee which has been functioning on an interim basis under the sponsorship of the National Health Council for a year, was fully organized. James Stone, program director of the National Tuberculosis Association, was made chairman to succeed Philip Mather, President of the National Health Council, who has served as chairman pro tem. Dr. G. F. Moench, Health Chairman of the Congress of Parents and Teachers, is vice chairman, and Martha Luginbuhl, Research Assistant of the A.P.H.A.'s Subcommittee on Local Health Units, secretary. A new agency, the National Sanitation Foundation, was welcomed to the committee, which now has representation from 51 national agencies. Of these, 28 are citizen agencies and 23 voluntary health and allied agencies.

An executive committee, including the officers serving ex officio, was chosen as follows:

Haven Emerson, M.D., Chairman, Subcommittee on Local Health Units
Mrs. Stephen Francisco, Public Welfare Chairman, General Federation of Women's Clubs
Harold Friermood, Secretary Health and Physical Education, National Board, Young Men's Christian Association
Mrs. Dorothy Hamilton, National Urban League
Harold Nutter, Lion's International
Joseph V. Tobin, American Federation of Labor

At this meeting Dr. Haven Emerson reviewed the progress of the local health units program from its inception with the A.M.A. and A.P.H.A. resolutions of 1942. Among the developments he reported were resolutions from about a dozen of the committee agencies urging the support of community activities for better local health services; the growth of state health councils; the discussion of the local health units program in the house organs of the various agencies; the programming of this project in national agency meetings, the leadership of voluntary or civic agencies in developing local public opinion—the tuberculosis association in one place, the A.M.A. Women's Auxiliary in another, Lion's International in another, League of Women Voters in still another, and many others; the sponsorship of the Local Health Services Bill of 1948 by the National Congress of Parents and Teachers, and its plans for reintroduction in the 81st Congress; the growing provisions for state aid to local health services as in California, which passed a state aid law in 1947 and backed it up with a $3,000,000 appropriation and provisions for minimum standards as a prerequisite for aid; the growth of consolidated health districts in many states, notably Florida and Michigan, and the resolutions of the Local Health Units Section of the National Health Assembly. These and many others show "a definite spirit of excitement quite in contrast to the inert attitude of 7 or 8 years ago."

Dr. Emerson pointed out that 44 of the 48 state legislatures would meet in 1949 and that this was therefore the crucial year for catching up on legislative lags—permissive health unit legislation in some states, and addition to or clarification of such legislation in others, definite provision for state aid in many, removal of salary ceilings in several, most notably Kentucky. He urged every national agency to keep its

state and local branches alerted to the status and significance of legislation in their own states.

Reported also was a local health units story to appear in *Colliers Magazine* of January 22. This was planned and written by a free lance writer who saw its possibilities and without special "inside" influence from the committee. Another free lance writer is exploring the same idea with a monthly popular magazine. These are the signs, according to Dr. Emerson, that indicate national recognition of the importance of the Princeton group who are now the facilitating agencies for carrying this program to its goal.

Among the actions taken by this meeting through resolution, formal motion, or common consent were the following:

1. Creation of a subcommittee on educational materials which would evaluate existing pamphlets on what to expect of a community health department and what is needed to get one, and to prepare further educational aids if they are found to be necessary. In this project close coöperation may be expected from the U. S. Public Health Service. A need was expressed particularly for a very short and simple outline that would be universally read and understood by club members. The members of this subcommittee, appointed by the Chairman, Mr. Stone are:

Mrs. Dwight Perrin, Chairman, Board Member, American Social Hygiene Association
H. M. Graning, M.D., Director of Local Health Services, U. S. Public Health Service
Mrs. Irmagene Holloway, Health and Safety Chairman, National Federation of Business and Professional Women's Clubs
G. F. Moench, M.D.
Lee A. Rademaker, M.D., Member-at-Large, National Advisory Committee on Local Health Units
Mrs. Roy Weagly, President, Associated Women of the American Farm Bureau Federation

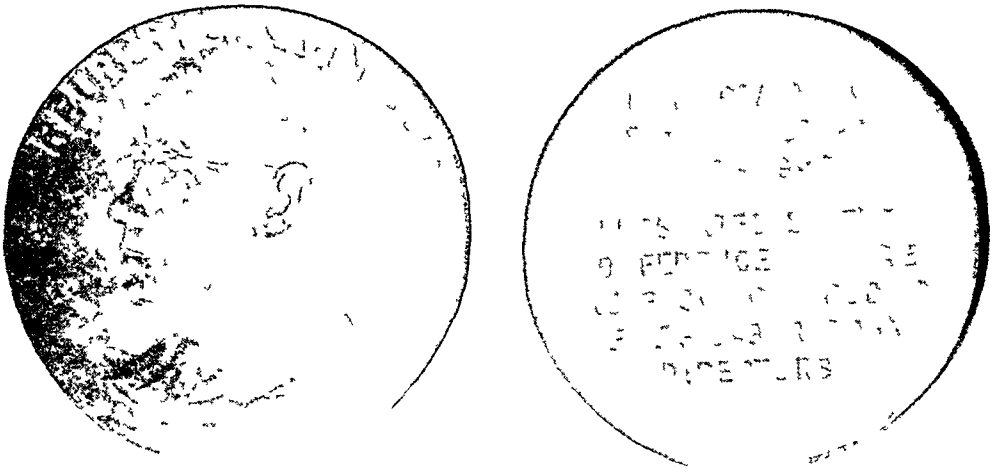
2. Commendation to the National Health Council staff for the two regional conferences already held and a recommendation that others be planned at suitable times and places, particularly in relation to regional and state public health association meetings.

3. Reaffirmation of last year's resolutions calling upon all the agencies to use appropriate means within their power to get coverage of the entire nation with local health units under competent direction.

4. Reëndorsed the resolution of last year, "that representatives at this meeting, in their individual capacities, recognize the necessity for federal assistance to states to complete the coverage of their respective populations and areas with full-time local health units under professional direction."

5. The Congress of Parents and Teachers was commended for its plan to reintroduce the Local Health Services Bill of 1948 in the 81st Congress.

6. The *Bulletin on Local Health Units* should be continued, approximately on a monthly basis.



7. A vote of appreciation to Haven Emerson, M.D., for his fruitful leadership of six years in this program.

8. The Secretary was instructed to record in the official minutes of the meeting a statement expressing deep appreciation of the group for the expert leadership given by Philip Mather to the National Advisory Committee on Local Health Units during this strategic period of early development and organization.

MICROBIOLOGICAL INSTITUTE IN NATIONAL INSTITUTES OF HEALTH

Plans for a Microbiological Institute in the National Institutes of Health, U. S. Public Health Service, were announced in October. In his announcement, Assistant Surgeon General R. E. Dyer, director of the National Institutes said: "The concentration of cancer, heart, and dental research in special institutes has made it necessary to regroup within the Microbiological Institute and the Experimental Biology and Medicine Institute, which was established last December, important research dealing with such diseases as malaria, polio, typhus, and the common cold, and a number of basic research studies in such fields as physics, chemistry, nutrition, metabolism, and pathology. This enables work in these diseases and fundamental research to go forward with the same intensified effort being given to cancer, heart, and dental problems."

PUBLIC HEALTH LABORATORY DIRECTORS HONOR DR KAHN

The Conference of State and Provincial Public Health Laboratory Directors meeting in Boston November 7 at the time of the 76th Annual Meeting of the American Public Health Association devoted their 28th Annual Dinner to honor Dr. Reuben L. Kahn in commemoration of the 25th Anniversary of the first demonstration of the Kahn reaction. This was presented on October 10, 1923, in Boston before the 52nd Annual Meeting of the American Public Health Association.

The dinner which was presided over by Dr. I. H. Borts of Iowa City had as master of ceremonies Dr. F. R. Hassler of Oklahoma City. Dr. Kahn described his work with the serological test for syphilis and presented among others Miss Elizabth B. McDermott who has long been his associate.

Also in commemoration of this anniversary, the *Journal of the Michigan State Medical Society* devoted its October, 1948, issue to honoring Dr. Kahn, with scientific articles on the test and a bibliography of Dr. Kahn's books and articles, consisting of 170 titles.

The Conference of State and Provincial Public Health Laboratory Directors presented Dr. Kahn with a medallion bearing a relief portrait on one side and the commemoration of the 25th anniversary of the Kahn reaction on the other.

COURSE ON VIRUS RESEARCH

The Department of Microbiology of New York University College of Medicine announces an intensive course in the theories and techniques of virus research to be given from March 21 to June 3, 1949. The course, which is expected to occupy the full time of the student, will include lectures, laboratory work, and discussion Credit for two full courses will be given by the Graduate School of New York University. The laboratory work will include the techniques currently used with bacterial and mammalian viruses such as. methods of cultivation, purification. concentration, and assay of viruses, their serological reactions, and the hemagglutination. Because the number of students is limited to 12. early application

is recommended. Further information may be obtained from the Department of Microbiology, 477 First Avenue, New York 16, N. Y.

WESTERN BRANCH A.P.H.A. ACTIVITIES

Walter S. Mangold, the Secretary of the Western Branch, A.P.H.A., with offices at the School of Public Health, University of California, Berkeley, has announced that the 1949 Annual Meeting of the Western Branch will be held in Los Angeles with headquarters at the Biltmore Hotel, May 30–June 1, 1949. Special efforts are under way to make the program outstanding and the exhibit will be emphasized at the forthcoming meeting.

Mr. Mangold has announced the appointment, by George M. Uhl, M.D., President of the Western Branch and Health Officer of Los Angeles City, of the following committee chairmen:

Richard A. Koch, M.D., *Finance Committee*
Ellis Sox, M.D., *Membership Committee*
Charles M. Carpenter, M.D., *Program Committee*
Dorothy B. Nyswander, Ph.D., *Publications Committee*
Walter H. Brown, M.D., *Constitution Committee*

A News Letter to the members of the Western Branch is planned to acquaint all concerned with Western Branch activities.

Mr. Mangold announces that the 1948 *Annual* with the papers from the Salt Lake City meeting of the Western Branch in 1948 will shortly be published.

Mrs. Alice Harris, Berkeley, Assistant to the Secretary has been employed on a full-time basis as of October 1 to maintain continuity in the Branch office.

REORGANIZATION OF PITTSBURGH HEALTH DEPARTMENT

In October, 1948, the U. S. Public Health Service delivered to Mayor Lawrence of Pittsburgh (Pa.) a study of that City's Health Department, made by the Service under the direction of E. R. Coffey, M.D., medical director of District 1 of the Service.

Mayor Lawrence has reported that he will use the study as a guide in reorganizing the department. Several steps in the reorganization process have already been taken. In September, Erwin C. Drescher, Senior Surgeon, U. S. Public Health Service, became consultant to the Pittsburgh Health Department with a specific request by the Mayor for advice on the reorganization.

In the field of environmental sanitation, Herbert J. Dunsmore, formerly public health engineer of the Battle Creek-Calhoun County (Mich.) Health Department became Pittsburgh's Public Health Engineer in charge of all food, milk, housing, and other sanitary services of the department. Simultaneously, the Standard Restaurant Ordinance of the U. S. Public Health Service was adopted by the Pittsburgh City Council after a 9 month study during which Council members had visited St. Louis and other cities to see firsthand the operation of the grading and placarding system. Placarding will begin in Pittsburgh in January, 1950. In September, also, food inspectors were given an intensive 2 week training course by a training team of the U. S. Public Health Service.

Also in September, Janice Mickey, former director of public health nursing of the Rochester-Olmsted County (Minn.) Health Department, became Chief of Pittsburgh's Bureau of Public Health Nursing Services.

These new appointees and others of the Pittsburgh staff will lecture at the University of Pittsburgh as a part of the program of establishing a close relationship between the University Medical Center and the City Health Department.

RED SQUILL REFERENCE POWDER AVAILABLE

Although red squill is now readily

available for use in rodent control, difficulties have arisen because of the variable potency of separate batches. To help resolve these difficulties, the National Pest Control Association has developed a "tentative red squill reference powder" for testing the strength of squills. Test sets may be obtained from the National Pest Control Association, 3019 Ft. Hamilton Parkway, Brooklyn 18, New York, $2 per test; $1 in quantities of six or more.

CHICAGO SURVEY OF Q FEVER

Representatives of management and labor in the meat and dairy industries met at the Chicago Health Department recently to arrange for the collection of 1,000 blood samples for a survey of Q fever in the city, particularly to determine whether the disease is an occupational hazard to livestock workers.

For the survey Chicago City Health Department teams are collecting blood samples from packinghouse, slaughterhouse, and rendering plant workers and workers on dairy farms, at raw milk receiving stations and pasteurization plants. Although no cases diagnosed as Q fever were reported in 1947 or in 1948, 30 cases were reported among Chicago packinghouse workers in 1946.

MILK AND FOOD SANITATION RESEARCH SYMPOSIUM

A two day symposium on recent research in milk and food sanitation is being sponsored by the Sanitation Study Section of the Division of Research Grants and Fellowships, U. S. Public Health Service, January 26–27, 1949, to be held in the auditorium of the U. S. Department of Commerce, Washington, D. C. The program calls for a discussion of milk and related topics on January 26 and of other foods on January 27. Further information may be obtained from Henry L. Roahrig, Executive Secretary of the Sanitation Study Section in Washington.

HEALTH CONSERVATION FOUNDATION PROPOSED

A group of four men in Philadelphia —S. S. Huebner, Wharton School of Finance; William Harvey Perkins, M.D., Dean of Jefferson Medical School; William G. Schmidt, and E. Burke Wilford —are the founders of a proposed Health Conservation Foundation to make "preventive medical care available to the average person in America. The goal to be envisioned is preventive medicine for every American by 1970 at least." The argument they present to life insurance companies, which constitute their first line of attack, is that if fire insurance companies can spend, as they do, an average of 5 per cent of their gross premium on fire prevention education, life insurance companies should be able to spend one per cent of premium income on preventive medicine.

The immediate objectives as outlined by Mr. Wilford are:

1. To educate the medical profession in the necessity and administration of successful periodic examinations.
2. To raise $500,000 annually for expansion of chairs of preventive medicine in American medical colleges.
3. To study and perfect periodic medical examinations.
4. To urge the life insurance industry to earmark money for the use of policy holders in health conservation. A goal of at least 100 million dollars annually has been set.
5. To keep the individual and the doctor relation on an American basis and to improve this relation constantly.

The pamphlet *How to Make Individual Preventive Medicine Economically Possible* and other information are available from Health Conservation Foundation, Wilford Building, Philadelphia 4, Pa.

MENTAL HYGIENE UNIT HONORS PEDIATRICIAN DR. ALDRICH

C. Anderson Aldrich, M.D., Director of the Rochester Child Health Institute of the Mayo Clinic, Rochester, Minn., has won the Lasker Award of the Na-

tional Committee for Mental Hygiene for 1948. The winner received on November 4 the fifth annual prize in this field from Dr. George Baehr, President of the New York Academy of Medicine, at the committee's 39th annual luncheon in New York. Dr. Aldrich was cited for "outstanding accomplishments in the education of the physician in the psychological aspects of the practice of medicine."

As organizer four years ago of the Rochester Child Health Institute, Dr. Aldrich designed a preventive psychiatric and "well-child" service for children in a community of 30,000. In conjunction with the Mayo Foundation, he developed a training program in pediatric mental health. The program was said to have expanded and improved existing local facilities instead of developing new agencies.

SONOMA'S NEW HOME

The Health Department of Sonoma County, California, serving about 85,000 persons, moved into its new home recently. *California Health* reports the building was made possible through the plans presented to the board of supervisors by the health officer, Edith Young, M.D. When an additional $5,000 was needed to complete construction the Elks Lodge stepped forward and later equipped the plant and dedicated it. It was officially opened with a community party given by the citizens.

Described as a spacious, light, H-shaped building, it is located on the county hospital grounds. One wing houses an auditorium and the headquarters of the county tumor board. It also has a fenced-in outdoor play area for children immediately adjacent to the child health conference waiting room.

PALO ALTO DECIDES TO COÖPERATE

Palo Alto, Calif., with a 1940 population of less than 20,000 recently voted to combine its health services with those of Santa Clara County. Louis Olsen, the former Palo Alto Health Officer, is now Assistant Health Officer of the county. The contract for joint services became effective on August 1 and was recommended by the California State Health Department. The County Health Department now serves more than 100,000 persons. San Jose with more than 75,000 population maintains its separate city health department.

TUBERCULOSIS MANUAL FOR PUBLIC HEALTH NURSES

The Massachusetts State Department of Health recently issued a manual on tuberculosis control for public health nurses. The 94 page loose-leaf publication, prepared by Helen C. Reilly and Beatrice H. Ditto of the Bureau of Public Health Nursing, with the collaboration of Dr. Alton S. Pope of the Division of Tuberculosis, has a special chapter on the mass surveys that have been conducted in coöperation with the Massachusetts Tuberculosis League since 1942. Single copies are available for limited distribution.

AMERICAN UNION OF INDUSTRIAL MEDICINE

The Association has been informed that at the last meeting of the Argentine Congress of Industrial Medicine held in Buenos Aires in May, 1948, it was decided to establish the Union Americana de Medicina del Trabajo (American Union of Industrial Medicine) and that already eleven American countries are affiliated in the Union.

The purpose of the Union is to study the specialty of industrial medicine, to aid in propagating knowledge among medical and technical persons of the Americas, to stimulate the interchange of scientific publications and information, and to organize in alternate years an American Congress in one or another of the American countries.

The permanent General Secretary

named at the last meeting is Dr. Jose Pedro Reggi of Argentina, Arenales 981, Buenos Aires. A magazine, *Medicina del Deporte y del Trabajo,* is being published and a library has been established in this specialty.

According to Dr. Reggi, plans are being laid for the next meeting to be designated as the First American Congress of Industrial Medicine, to be held in Buenos Aires during October, 1949.

The American Union of Industrial Medicine wishes to establish personal and scientific relations with the members of the American Public Health Association, and they have filed with the Association office this information regarding the organization and constitution of the Union. North Americans are invited to attend the First Congress.

UNITED MINE WORKERS OF AMERICA WELFARE AND RETIREMENT FUND ALLOCATES REGIONAL STAFF

The United Mine Workers of America Welfare and Retirement Fund, Washington, of which Warren F. Draper, M.D., formerly of the U. S. Public Health Service, is Executive Medical Officer, announced recently the location selected for the headquarters and area medical offices of the Welfare and Retirement Fund as follows:

Asa Barnes, M.D., Louisville, Ky.
Deane F. Brooke, M.D., Beckley, W. Va.
William A. Dorsey, M.D., Denver, Colo.
Leslie A. Falk, M.D., Johnstown, Pa.
Lorin E. Kerr, M.D., Morgantown, W. Va.
John T. Morrison, M.D., Charleston, W. Va.
Herbert Scheffer, M.D., Birmingham, Ala.
Cecil A. Z. Sharp, M.D., St. Louis, Mo.
John D. Winebrenner, M.D., Knoxville, Tenn.

According to the *Washington Report on the Medical Sciences,* the UMWA Welfare and Retirement Fund is concerned in the main with pensions, disability benefits, death benefits, and medical, health, and hospital services for the members of the United Mine Workers of America. It has undertaken to provide a prepaid form of hospital service and medical attention in various districts and in all local unions. The Welfare and Retirement Fund is utilizing present medical and hospital facilities under conditions which aim at high standards of service.

DR. DOULL JOINS AMERICAN LEPROSY FOUNDATION STAFF

James A. Doull, M.D., Dr.P.H., Medical Director, U. S. Public Health Service, Washington, D. C., has been detailed, effective November 1, to the Leonard Wood Memorial (American Leprosy Foundation) which has headquarters at One Madison Avenue in New York City. The office of the Medical Director will be located in the Federal Security Building (Room 5721), Washington, D. C. pending establishment of permanent headquarters in Washington. Dr. H. Windsor Wade, formerly Medical Director of the Memorial, has been forced to relinquish the position because of ill health but will remain on the staff as Associate Director and Pathologist. Dr. John Hanks will continue in charge of the Memorial's Bacteriology Laboratory in the Department of Bacteriology and Immunology at Harvard. Dr. Ricardo S. Guinto will continue as epidemiologist.

STATE AND TERRITORIAL HEALTH OFFICERS

The Annual Meeting of the State and Territorial Health Officers Association was held in Washington in the middle of November and the following new officers were elected:

President—R. H. Hutcheson, M.D., Nashville, Tenn.
Vice-President—Wilton L. Halverson, M.D., San Francisco, Calif.
Secretary-Treasurer—R. L. Cleere, M.D., Denver, Colo.
Vlado R. Getting, M.D., Boston, Mass., and Carl N. Neupert, M.D., Madison, Wis., were elected to the Executive Committee.

According to the *Washington Report*

on the Medical Sciences, the Association resolved that the most urgent legislation in their particular field to confront the new Congress will be federal subsidies of local public health units throughout the country and the establishment of a Department of Health, Education and Security, headed by a Secretary as a Cabinet member.

The following resolutions were adopted:

WHEREAS the American Public Health Association has assumed proper leadership, through its Merit System Service, in developing examination services for the selection of professional public health personnel and has, in this process, made use of the skills and experience of public health workers throughout the country; and

WHEREAS the selection of the most highly qualified of the candidates for service in public health is basic to the effective functioning of public health programs; and

WHEREAS the effectiveness of this program is evidenced by the fact that 75 per cent of the states have made successful use of these examinations; and

WHEREAS there is no other source for such services available to health authorities; and

WHEREAS the Annual Service Plan has been developed by the Merit System Service to permit the wider use of examinations and has been endorsed by the Public Health Service, the Children's Bureau, and the Executive Board of the American Public Health Association; therefore be it

RESOLVED:

1. That the Association of State and Territorial Health Officers record their endorsement of the examination program of the Merit System Service of the American Public Health Association; and
2. That they affirm their belief in the effectiveness of these examinations as one inportant tool in the selection of qualified public health workers; and
3. That they urge participation by State Health Departments in the Annual Service Plan—not only so that individual states may benefit from the use of these examinations, but also so that the program itself may have the support which is necessary to insure its continued development and extension.

A second resolution follows:

WHEREAS human resources are the nation's greatest asset; and

WHEREAS the security and well-being of our country cannot be achieved unless basic public health services are available in every locality through adequately staffed and properly equipped local public health units; and

WHEREAS at present more than 40 million persons in the United States live in areas not served by local public health units and less than 10 million persons live in areas served by units which meet basic minimum public health standards; and

WHEREAS it is well known that annually thousands of persons die unnecessarily from causes that could have been prevented; and

WHEREAS many areas cannot with their own resources support local public health units staffed and equipped to the extent necessary for the provision of the basic public health services essential to the well-being of the community; now therefore, be it

RESOLVED that the provision of adequate local health services is of paramount importance and that it be given highest priority in improving the health of the people; and further be it

RESOLVED that the Association of State and Territorial Health Officers urge the states to

1. Enact legislation enabling the establishment of county and multi-county units where such authority does not now exist;
2. Develop state-wide plans for local health unit coverage;
3. Develop state financial assistance plans for equitable allocation of funds to local health units;
4. Extend every possible assistance to medical and nursing schools in the teaching of preventive medicine and public health to undergraduate students in order to encourage their interest in public health as a career;
5. Assist in the development of local health councils;
6. Develop competent field training centers; and be it further

RESOLVED that the Association of State and Territorial Health Officers urge the support of federal legislation for the provision of

1. Financial assistance to State Health Departments for developing and maintaining local public health units organized to provide basic full-time public health services in all areas of the Nation, and, in the training of all types of personnel for local public health unit work; and be it further

RESOLVED that the Public Health Service, the Children's Bureau, all State Health Departments, voluntary organizations, and the general public be urged to support such legislation.

EVELYN BURKE R.

PROGRESS UNDER THE FEDERAL HOSPITAL CONSTRUCTION ACT

The U. S. Public Health Service Division of Hospital Facilities has reported progress under the Hill-Burton Act up to the end of October, 1948. Five hundred forty applications have been approved by the Surgeon General, of which there are now under construction more than 100.

According to the *Washington Report on the Medical Sciences,* the total estimated cost of the 540 is in excess of 301 million dollars, of which the federal share will be approximately 92 million. All but 124 of the projects are new general hospitals or additions to present plans. The remainder consists of 27 mental hospitals, 16 for tuberculosis, 9 for chronic disease, 66 health centers, 3 nurses' homes and 3 health department laboratories. It is said that two-thirds of the prospective new general hospitals will be erected in towns of less than 5,000 population and that only 15 are intended for cities of 50,000 population or more.

DR. ANDREWS TO IRAN ON MEDICAL MISSION

Justin Andrews, Sc.D., Executive Officer, Communicable Disease Center, Atlanta, has been borrowed by the U. S. State Department to make a one month survey of the worsening malaria problem in Iran, which requested the study and will foot the bill. Dr. Andrews' job will be to formulate a malaria abatement program, then return and marshal an American force which would go to Iran, probably in March, for the purpose of training native technicians in malaria control techniques. The plan is to have the campaign under full steam by midsummer. Dr. Andrews possesses wide experience as a malaria eradication expert, having devoted his Army career to the work in Mediterranean and Southwest Pacific areas during World War II. He was temporarily detached from his regular duties to take the assignment to Iran.

NATIONAL GASTROENTEROLOGICAL ASSOCIATION 1949 AWARD CONTEST

The National Gastroenterological Association announces its Annual Cash Prize Award of $100 and a Certificate of Merit for the best unpublished contribution on Gastroenterology or allied subjects. Certificates will also be awarded those physicians whose contributions are deemed worthy. The award will be made at the Annual Convention Banquet of the Association in October, 1949.

Contestants residing in the United States must be members of the American Medical Association. Those residing in foreign countries must be members of a similar organization in their own country. All entries for the 1949 prize should be limited to 5,000 words, be typewritten in English, prepared in manuscript form, submitted in five copies accompanied by an entry letter, and must be received not later than April 1, 1949. Entries should be addressed to the National Gastroenterological Association, 1819 Broadway, New York 23, N. Y.

MASSACHUSETTS PUBLIC HEALTH ASSOCIATION

At the annual dinner meeting of the Massachusetts Public Health Association, held at the University of Massachusetts in June, the following officers were elected:

President: Vlado A. Getting, M.D., State Commissioner of Public Health
First Vice-President: Mary E. Spencer, Ph.D.
Second Vice-President: Leon A. Bradley, Ph.D., Head, Department of Bacteriology and Public Health, University of Massachusetts
Treasurer: Catherine Atwood
Secretary: S. L. Skvirsky, M.D.
Executive Secretary: Mrs. Elizabeth K. Caso, Harvard School of Public Health, 695 Huntington Avenue, Boston
Section chairmen:
Health Officers—Alfred L. Frechette, M.D.

Laboratory—John M. Newell
Food and Nutrition—Stuart B. Foster, Ph.D.
Sanitation—Robert E. Bemis
Maternal and Child Health—Stuart S. Stevenson, M.D.
Public Health Nursing—Alice C. MacKinnon, R.N.
Health Education—Beryl J. Roberts, M.A.

The next annual meeting will be held at Amherst in conjunction with the third annual Massachusetts Public Health Conference June 15–17, 1949.

NORTH DAKOTA PUBLIC HEALTH ASSOCIATION

The Fifth Annual Meeting of the North Dakota Public Health Association, an Affiliated Society of the A.P.H.A., was held in Minot on October 28 and 29. The two day meeting included a joint meeting with the North Dakota Health Officers Association and the Northwest District Medical Society, and sectional meetings of sanitarians, nurses, laboratory personnel, and lay persons. The registered attendance was 124.

The following new officers were elected:

President—Melvin E. Koons, Grand Forks
Vice-President—Everett Lobb, Fargo
Treasurer—Milla Tollefson, Bismarck
Secretary—Margaret L. Watts, Bismarck

Bernadine Cervinski was elected to represent the North Dakota society on the Governing Council of the American Public Health Association.

PERSONALS

VESTA BOWDEN, R.N.,† formerly Maternal and Child Health Nursing Consultant and Assistant Director of the Public Health Nursing Section, was appointed Director of the Public Health Nursing Section of the Colorado State Health Department, Denver.

GEORGE R. COWGILL, Ph.D.,* Professor of Nutrition, Yale University, New Haven, Conn., was presented recently with the Fourteenth Annual Scientific Award of the Grocery Manufacturers Association of America, Inc., "in recognition of his contributions to the science of nutrition, particularly for his research in the functional rôle of Vitamin B_1, his success as a teacher of young biochemists, and his editorial work for the Journal of Nutrition."

GERALD J. COX, Ph.D., has been appointed Director of Dental Research in the University of Pittsburgh's School of Dentistry, Pittsburgh, Pa. He has held the position of research chemist with the Corn Products Refining Company, Argo, Ill., since 1944.

MAJOR GENERAL FRANCOIS DAUBENTON has been named chief of the WHO mission to Ethiopia, succeeding D. A. MESSINEZY,* assigned to WHO's secretariat in Geneva. General Daubenton is former Director of the Medical Services of the Royal Netherlands Army.

EARL DEVENDORF,* of Schenectady, N. Y., who for more than 20 years has been Assistant Director of the Bureau of Environmental Sanitation, New York State Department of Health, Albany, has been promoted to become Director of the Bureau, succeeding CHARLES A. HOLMQUIST, of Albany who retired October 31.

WILLIAM J. DOYLE, M.D., formerly in private practice and county health officer in Montana, has been appointed as Deputy District Health Officer, Washington-Yamhill District Health Department in Oregon.

JOHN M. GLENN,† the first Executive Director of the Russell Sage Foundation and now a Trustee, was honored by a number of friends and associates at an informal dinner at the Harvard Club in New York City, October 26, on the occasion of his approaching 90th birthday.

PROFESSOR EDMOND GRASSET, the Director of the new Institute of Hygiene

in Geneva, Switzerland, has been visiting the schools of public health in North America as the guest of the Rockefeller Foundation.

RILEY H. GUTHRIE, M.D., on November 1, became special mental hospital consultant, Mental Hygiene Division, U. S. Public Health Service, Washington, D. C. He will conduct surveys of mental hospitals and provide consultive services regarding hospital administration, care of patients, and other problems of mental hospitals to state governors and administrators of state mental hospitals.

RUTH BORING HOWARD, M.D., is the new Director of Maternal and Child Health Section of the Colorado State Health Department, Denver. Since 1942, she has been in the U.S.P.H.S. with the rank of Surgeon, and among her assignments was that of Medical Director in a Venereal Disease Rapid Treatment Center.

BRIG. GEN. EDGAR ERSKINE HUME, M.C., U.S.A.,* received the Gorgas Award in San Antonio, Tex., on November 12, at the meeting of the Association of Military Surgeons in recognition of his services in the Medical Corps since 1916 and with special reference to the control of typhus fever.

WILLIAM KILOH, Executive Secretary of the Humboldt County, California, Tuberculosis and Health Association, has resigned to accept a position with the Alaska Health Department.

LLEWELLYN E. KLING, M.D., M.P.H.,† has resigned as Medical Director of the Planned Parenthood Federation, New York, N. Y., to become Associate Professor of Public Health Education and Head of the Division of Public Health Education, Columbia University School of Public Health, New York. Dr. Kling served as a county health officer in Nebraska, was with the U.S.P.H.S. during the war. He is a graduate in public health from the Columbia School.

AMEDEE S. LANDRY, Senior Chemist, Division of Industrial Hygiene, New Hampshire State Health Department, has resigned to become Industrial Hygiene Chemist with the Institute of Inter-American Affairs. Mr. Landry will be assigned to the Peruvian Government and will be stationed at Lima, Peru.

OSCAR LOTZ, M.D., Executive Secretary of the Wisconsin Anti-Tuberculosis Association, was named President of the Mississippi Valley Conference on Tuberculosis at the Conference's annual meeting in September.

HELEN LOVELL, on October 1 was appointed Nutritionist for the Iowa State Department of Health, Des Moines. She recently completed her work on her Master of Science degree at the University of Nebraska, Lincoln.

ESCHSCHOLTZIA LUCIA, PH.D.,* Consultant in Statistical Research, and former Professor of Biometry at the University of California, is retiring from the California State Department of Public Health, Los Angeles, after 2 years of service.

ELEANOR J. MACDONALD,* Research Statistician with the Division of Cancer and Other Chronic Diseases, Connecticut State Health Department, Hartford, left October 1 to become Research Statistician at the M.D. Anderson Hospital for Cancer Research, Houston, Tex.

C. A. MCINTYRE, M.D., has begun his duties as Health Officer for the San Juan Basin Health Department including Archuleta, Dolores, LaPlata, Montezuma, and San Juan Counties in Colorado.

MARY E. PARKER, R.N.,* has been promoted from Assistant Director, Bureau of Public Health Nursing, New York State Department of Health,

* Fellow A.P.H.A.
† Member A.P.H.A.

Albany, to become Director, effective January 1, succeeding MARION W. SHEAHAN, R.N.,* retired. Miss Parker took her postgraduate work at Yale and at the University of Minnesota.

MARION W. SHEAHAN, R.N.,* on December 31, 1948, retired as Director of the Bureau of Public Health Nursing in the New York State Department of Health. Miss Sheahan has served for 28 years and as Director since 1932. She is immediate Past-President of the N.O.P.H.N., and has served as Vice-President of the A.P.H.A.

EDMOND B. SINCLAIR, M.D., was appointed as crippled children's physician with the Connecticut State Department of Health, Hartford. Dr. Sinclair studied at the Yale University School of Medicine, Department of Public Health, for the academic year 1947–1948.

MARY E. SOULES, M.D.,† North Dakota State Health Department, is now Deputy Health Officer, Multnomah County (Oregon) Health Department.

JAMES H. STEELE, D.V.M.,† of the staff of the U. S. Public Health Service Communicable Disease Center, was appointed as Chairman of the U. S. Delegation to the Second Inter American Congress on Brucellosis held in Argentina, November 17–26.

KEITH T. SWARTZ, PH.D., research specialist on canned foods, has joined the staff of the Animal Products Branch of the Quartermaster Food and Container Institute for the Armed Forces, Chicago.

HENRY C. SWEANY, M.D.,† of Chicago, was awarded the 1948 Dearholt Medal, given annually by the Mississippi Valley Conference on Tuberculosis for outstanding work in tuberculosis control. Dr. Sweany is Medical Director of Research, Municipal Tuberculosis Sanitarium, Chicago, and served for 5 years as a member of the N.T.A.'s Committee on Medical Research.

L. E. TAYLOR, of the Detroit Edison Company, became the new President of the Illuminating Engineering Society, New York, N. Y., at the 1948 Conference of the Society in Boston in October.

ALEXANDER WITKOW, M.D.,* formerly Director of Local Health Administration, West Virginia State Health Department, became Health Commissioner of Worcester, Mass., on October 1.

ALASKA HEALTH DEPARTMENT—NEW STAFF MEMBERS:

PENELOPE EASTON, M.P.H.,† Dietary Consultant, to advise hospitals, institutions, and schools on nutrition problems.

LAURIS S. PARKER, Engineering Aide, to assist in general sanitation activities and the preparation of sanitation educational materials at the Juneau office.

ALFRED BAKER,† Sanitarian, for the Ketchikan area. He served for 3 years each in the Navy Medical Corps and the Fisheries Research Laboratory at Ketchikan.

GERTRUDE HANSEN, Public Health Nurse, to conduct itinerant nursing services from Haines. She has been with the Milwaukee City Health Department for the past 12 years.

MARY BRIMBERRY,† Public Health Nurse, to serve in the Interior. She spent 13 years with the Chicago Visiting Nursing Association.

GEORGIA STATE HEALTH DEPARTMENT (ATLANTA)—APPOINTMENTS:

LILLIAN M. BISCHOFF,† recently returned from 2½ years as chief nurse in the WHO I.C. Field Mission to Ethiopia, has been appointed Associate Director in the

* Fellow A.P.H.A.
† Member A.P.H.A.

State Health Department Division of Public Health Nursing.

DOROTHY F. JOHNSTON, Assistant Nurse Officer, U.S.P.H.S., has been transferred from Alto Rapid Treatment Center to the Georgia State Health Department, Venereal Division, as Consultant.

LITA L. KORBE, recently Director of Public Health Nursing, University of Georgia, has been appointed as Regional Public Health Nursing Consultant in the State Health Department.

Deaths

JOSEPH F. BREDECK, M.D., D.P.H.,† died October 4. Dr. Bredeck was Health Commissioner of St. Louis, Mo. (Health Officers Section.)

ANDREW G. DUMEZ, M.D., a member of the Maryland State Council on Medical Care since the appointment of that group in 1945, died suddenly on September 27. Dr. DuMez, who was appointed to the council as a representative of the Maryland Pharmaceutical Association, was Dean of the University of Maryland School of Pharmacy and a Past-President of the American Pharmaceutical Association.

WILLIAM A. EVANS, M.D., former Health Commissioner of Chicago, and President of the Chicago Medical Society, and for 23 years editor of the Chicago Tribune's "How to Keep Well" column, died November 8 at the age of 83.

JOHN TEMPLE GLENN, JR.,† head of the Production Laboratory of the Sharp and Dohme Laboratories in Pennsylvania, died last summer after a long illness. (Laboratory Section.)

JESSE LYNN MAHAFFEY, M.D.,† New Jersey State Health Director from 1931 until the reorganization of the Health Department in 1947 under New Jersey's new Constitution, died November 1. He was Acting State Health Commissioner of the reorganized department until June 2, when DANIEL BERGSMA, M.D.,* was sworn in as Commissioner. (Health Officers Section.)

MARY ADELAID NUTTING, internationally known leader in nursing education and Professor Emeritus of Teachers College, Columbia University, New York N. Y., since 1925, died October 3 in her 90th year after a prolonged illness. Her home was at Emerson Hall, Teachers College, Columbia University.

DON C. PETERSON, M.D., M.P.H.,* State Registrar of Vital Statistics, Tennessee State Department of Health, Nashville, died June 13, 1948. (Vital Statistics Section.)

Announcing the publication of

DIAGNOSTIC PROCEDURES IN VIRUS AND RICKETTSIAL DISEASES

This handbook, prepared by the Committee on Virus and Rickettsial Diseases of the Laboratory Section and edited by the Chairman of the Committee, Thomas F. Francis, Jr., M.D., details procedures which can be employed and interpreted by laboratory workers in the diagnosis of sixteen virus diseases. The diseases selected are essentially those of man for which procedures are available for use in a diagnostic laboratory.

Each of the sixteen sections has been written by an authority in the field. Much of the experience of each author has been contributed to his chapter and as a result the entire volume constitutes a compilation of methods proved by actual experience.

The volume has grown out of a recognized need for a publication of collected methods and has developed from a round table presentation at the Annual Meeting of the American Public Health Association in 1946. The methods are not presented as standards but are those most currently useful.

Members of the committee who have contributed and their subjects are as follows:

Psittacosis
K. F. Meyer, Ph.D., M.D. and B. Eddie, Dr.P.H.

Lymphogranuloma Venereum
Geoffrey Rake, M.B.

Trachoma and Inclusion Blennorrhea
Phillips Thygeson, M.D.

Variola and Vaccinia

THE NINTH EDITION

of

STANDARD METHODS FOR THE EXAMINATION OF DAIRY PRODUCTS

is now available

This manual, prepared by the Committee on Examination of Milk and Milk Products, outlines procedures for the routine microbiological and chemical examinations of the more common dairy products used as food. It includes directions for enumerating, isolating, and identifying members of the coliform group, *Brucella,* streptococci, tubercle bacilli, *Salmonella,* pathogenic *Shigella,* and enterotoxigenic staphylococci.

The resazurin reduction method for the examination of fluid milk is included in this edition. Procedures are given for the examination of condensed milk, dried milk, evaporated milk and of fruits, nuts, flavoring and coloring materials, eggs and egg products, sweetening ingredients and stabilizers when used as ingredients in frozen desserts.

The primary aim in the new edition is to aid the laboratory worker by maintaining uniformity of arrangement and style, by using a system of simple cross references, and by improving the index. To do this, the first chapter on "Selection and Interpretation of Quality Tests" is organized for the guidance of the administrator. The succeeding twelve chapters, now relatively free from interpretive and explanatory matter, provide tried and tested methods for the laboratory worker. A group of "Screening Tests," which do not have approval for unqualified use, but which permit more frequent examinations than otherwise could be made, appear in the last chapter.

The thirteen chapter headings are listed below.

1. Selection and Interpretation of Quality Tests
2. Microbiological Methods for Milk and Cream
3. Detection of Special Bacterial Groups or Species
4. Microbiological Methods for Butter
5. Microbiological Methods for Cheese
6. Microbiological Methods for Frozen Dessert Ingredients
7. Microbiological Methods for Frozen Desserts
8. Sterility Tests for Dairy Equipment
9. Tests for Sediment and Extraneous Matter in Dairy Products
10. Determination of Vitamins
11. Phosphatase Methods to Determine Pasteurization
12. Chemical Methods
13. Screening Tests

373 pages, 37 illustrations Published 1948 Price, $4.00

For UNIVERSAL UNIFORMITY
IN YOUR LABORATORIES
... Feed PURINA LABORATORY CHOW

Controlled conditions with live animals are hard to perfect. Simultaneous work in several laboratories across the country makes it even more difficult. But when you feed Purina Laboratory Chow and *recommend it to other labs* with whom you exchange data, you can be sure of dietary uniformity. Purina Laboratory Chow is specially made for laboratories, on a constant formula for nation-wide distribution. Feed this precision-made ration in your laboratories.

WHY MANY LEADING NOSE AND THROAT SPECIALISTS SUGGEST

"change to PHILIP MORRIS"*

Where smoking is a factor in a throat condition, the physician may advise "Don't Smoke." But where the patient persists, many eminent specialists suggest "*Change to* PHILIP MORRIS"... the one cigarette proved definitely less irritating.** Perhaps you too will find it advantageous to "*Change to* PHILIP MORRIS." For *all* smokers, Philip Morris is by far the wisest choice.

PHILIP MORRIS

35 YEAR INDEX

OF

American Journal of Public Health

Volumes 1 to 35 for the Years 1911 to 1945

All of the literature published on a given subject in the Journal during the years 1911 through 1945 will be found in one place. A complete Author's index is also included. The *Index* makes available a vast storehouse of valuable information contained in the fifty thousand pages published during this period. The tremendous task of preparing the *Index* was done by Louise Pickens Tanner, Ph.D., and Fred W. Tanner, Ph.D.

340 Pages — 6¾ x 9¾ — Bound in Buckram

Price $7.00

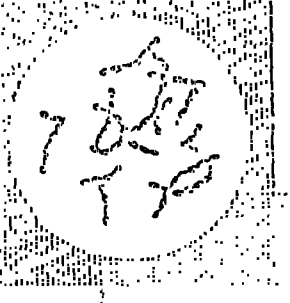
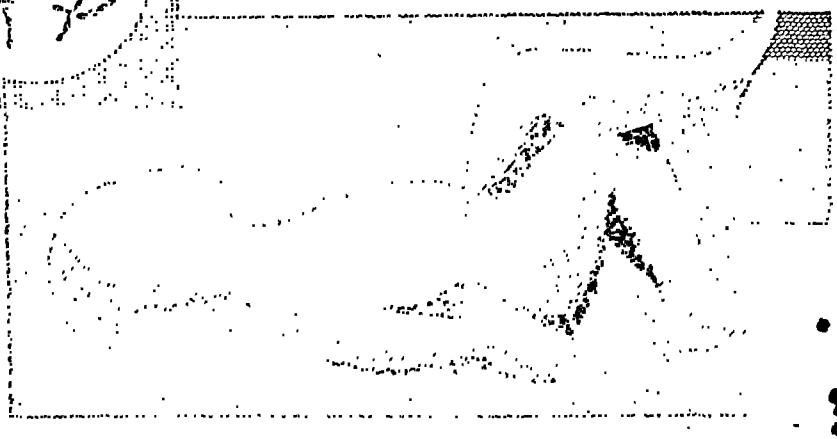
and THE NATION'S HEALTH

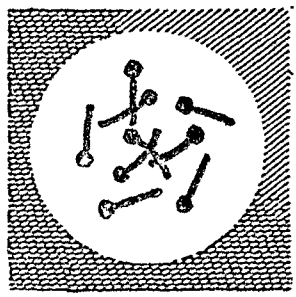




Volume 39 FEBRUARY, 1949 Number 2

Published Monthly at 374 Broadway, Albany 7, N. Y., by the

AMERICAN PUBLIC HEALTH ASSOCIATION

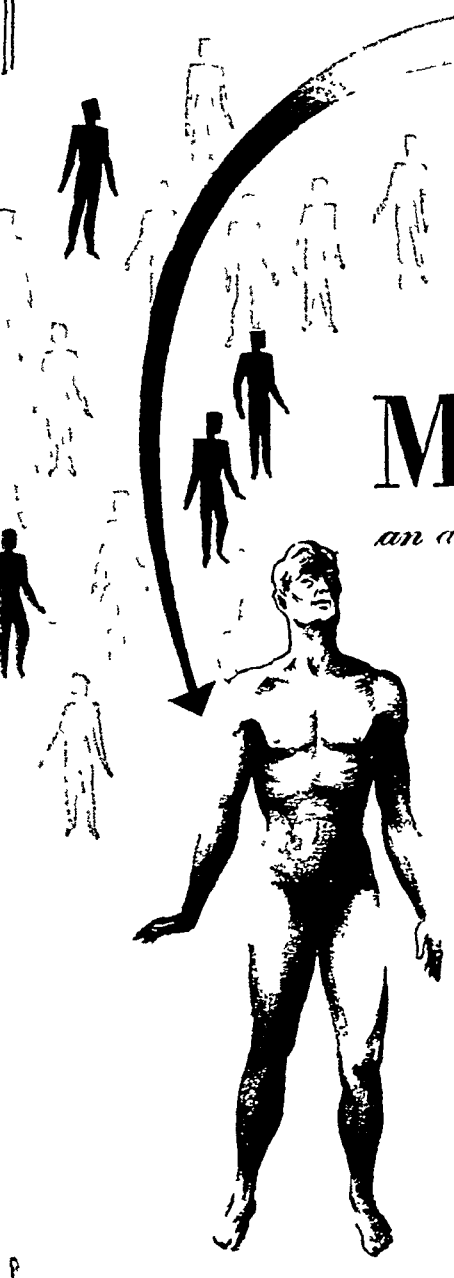


1790 Broadway (at 58th Street), New York 19, N. Y.

Three immunities with three 0.5 cc. injections

Protection against three organisms—C. Diphtheriae, Cl. Tetani, and H. Pertussis—is conveniently provided by *Diphtheria and Tetanus Toxoids Alum Precipitated and Pertussis Vaccine Combined Squibb* given in three doses of 0.5 cc. each at monthly intervals.

Among its many advantages are:



Greater Convenience to patient and physician alike
Less Discomfort to the patient
Fewer Injections and hence lower expense to the patient
Lower Expense of administration for institutions and physicians
Pharmaceutical Elegance—milky suspension, exceptionally fluid.

DIPHTHERIA AND TETANUS TOXOIDS
ALUM PRECIPITATED
AND PERTUSSIS VACCINE COMBINED

In 1.5 cc. vials, providing 1 complete immunization
In 7.5 cc. vials, providing 5 complete immunizations

SQUIBB

criteria in syphilotherapy

"Therefore, more than in any other disease, it is necessary in the treatment of an individual patient with syphilis to follow a therapeutic regimen which, after *long-term study* in *large series of patients*, has been established as *satisfactory* for the particular type of syphilis under consideration."*

MAPHARSEN®

an arsenical of choice in the treatment of syphilis

long-term study

More than a decade of clinical evaluation.

large series of patients

Over two hundred million injections already administered.

satisfactory

High therapeutic effectiveness with notable safety in causing disappearance of spirochetes, healing of lesions and reversal of seropositivity in a large percentage of cases.

MAPHARSEN (oxophenarsine hydrochloride, P. D. & Co.) is supplied in single dose ampoules of 0.04 Gm. and 0 06 Gm., boxes of 10, and in multiple dose ampoules of 0 6 Gm. in boxes of 10.

6 OUT OF EVERY 10 CASES OF..

MEASLES WILL OCCUR IN THE NEXT 3 MONTHS

You can prevent or modify measles without fear of side reactions

There's one sure way of silencing crying youngsters and nervous mamas who complain about reactions – specify Cutter Immune Serum Globulin–Human. Successful results with this product are not happenstance. They come from:

1. The right raw material—fresh venous blood from normal donors.
2. The water-clarity of a hemolysis-free and non-pyrogenic product.
3. The concentration of 160 mgm. per cc. of gamma globulin—maintains consistent globulin potency yet permits low volume adjustable dosage:

For prevention—
0.1 cc. Immune Serum Globulin
For modification—
0.02 cc. Immune Serum Globulin
} *intramuscularly, per pound body weight*

Prepare now for measles' peak season just ahead. Notify your pharmacist the amount of gamma globulin you expect to use—and specify Cutter.

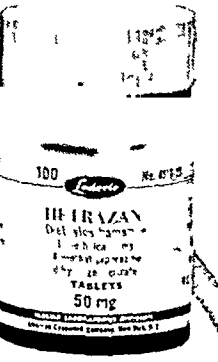
A Single Injection Every Other Day

Antibiotic therapy is greatly simplified when C.S.C. Crystalline Procaine Penicillin G in Peanut Oil with aluminum monostearate is prescribed. A single 1 cc. injection (300,000 units) produces therapeutic blood levels for 96 hours in over 90% of patients, *and for 48 hours in all patients.* For certainty of therapy, this preparation need not be given, as a rule, more often than once every other day.



Crystalline Procaine Penicillin G in Peanut Oil-C.S.C. contains 300,000 units of micronized procaine penicillin per cc., together with 2% aluminum monostearate for producing a thixotropic suspension. This outstanding penicillin preparation is free flowing and requires no refrigeration. It is indicated in the treatment of most infectious diseases amenable to penicillin therapy.

Crystalline Procaine Penicillin G in Peanut Oil-C.S.C. is available at all pharmacies in economical 10 cc. size rubber-stoppered vials (300,000 units per cc.). Also in vials containing 300,000 units (1 cc.), in boxes of five vials.

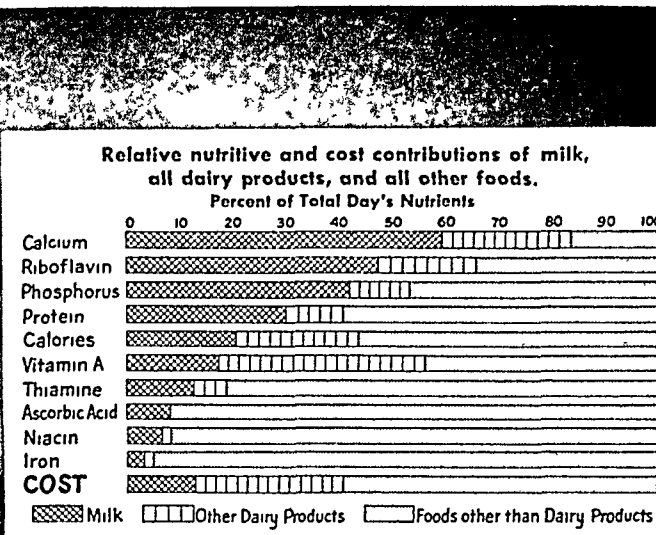
Stability in the Tropics

This new organic compound may be given easily by mouth, is almost immediately effective against the microfilariae in the blood stream and tissues, and is stable at the high temperatures that prevail in the tropics. It tends to end infestation with bancroftial filariae in 3 to 4 weeks and may be used to stamp out the infestation in whole populations.

Clinical tests made in India, Africa, the South Pacific, the West Indies, and Central America have established its clinical use.

PACKAGES: *Bottles of 100 and 1000 tablets*

*Reg U.S Pat Off.



High power photomicrograph (X 210) of microfilaria of W. bancrofti *in human blood. The red blood cells have been dissolved, leaving only the microfilaria and the white blood cells.*

This chart shows the nutritional contribution and comparative economy of dairy products and all other foods in a good average day's meals planned to follow the Basic Seven food pattern

Milk and Its Products are an Economical Basis for Daily Meals*

In planning meals, each food must be evaluated for its relative cost and its potential benefit to the body.

Milk and its products raise the food value of meals in each of the major aspects of nutrition . . . energy, proteins, minerals and vitamins. The chart above shows that milk and its products—cheese, ice cream and butter—in recommended amounts, can supply well over half of the day's total needs for calcium, phosphorus, riboflavin and vitamin A, and important amounts of other essentials, at considerably less than half of the day's total food cost. The chart demonstrates the fact that milk and its products are an economical basis for nutritious daily meals.

Milk's Food Value is High—Milk is an outstanding example of a food which contributes many times over its original cost in terms of bodily benefits. Without milk it is almost impossible to obtain the recommended daily amounts of calcium from other foods. Needed amounts of riboflavin and protein also are difficult to obtain without milk. In addition to its many *known* benefits, milk also is believed to contain additional nutritional factors whose identity and exact function are not yet fully established. Scientists are constantly carrying on research to bring forth the final significance of milk's nutritional role.

Milk Provides Generously for Its Own "Family"—Milk passes along to its products varying combinations of its nutritive elements. Cheese inherits much of the high quality protein, as well as substantial amounts of calcium and phosphorus. Ice cream, too, retains much of the protein content of milk, and helps increase the calcium and vitamin A intake. Ice cream is also a good source of riboflavin and recently has been shown to contain a highly utilizable form of this vitamin. Butter is a nutritious food in its own right. It is a splendid source of vitamin A and provides needed food energy in a delicious, digestible form.

**Milk is an Economical Food.* Dairy Council Digests. 20.2 (Nov.) 1948.

New Light on the Food Value of Ice Cream

Recent nutrition research has produced new evidence of the excellent food value of ice cream.

The substantial contribution ice cream can make to our dietary needs was assumed long ago from calculations of the food value of ice cream's ingredients. Now, however, actual analyses of commercial ice cream itself have shed new light on its food value. These analyses show that, in general, we had underestimated the nutritive content of ice cream. *This was particularly true of riboflavin and vitamin A.*

By actual analysis of average vanilla ice cream, values for calories, protein, fat, three important minerals, and five essential vitamins were obtained by Dahlberg and Loosli.* The riboflavin content is now realized to be much higher than the value formerly arrived at by calculation. Vitamin A is higher, too. This is because most ice cream is made with milk fat produced in summer months when the vitamin A content is above average levels.

The presence of a nutritive element in a particular food is merely the first step in determining its ultimate beneficial effect. The nutrient must be in a form which is readily assimilated by the body. In this respect, the riboflavin in ice cream is of a superior nature.

A study conducted by Everson and co-workers** on eight women subjects reveals that the riboflavin in ice cream is utilized almost 100% by the body—*nearly as well utilized as the pure crystalline form of the vitamin.* Utilization from servings of two other test foods, which were similar to the ice cream in riboflavin content was less than 50%.

These studies offer tangible evidence of ice cream's importance as an *everyday* food. Ice cream can play an important role in promoting general well being for all and can help meet the special diet demands of pregnant women, convalescents, and aged persons.

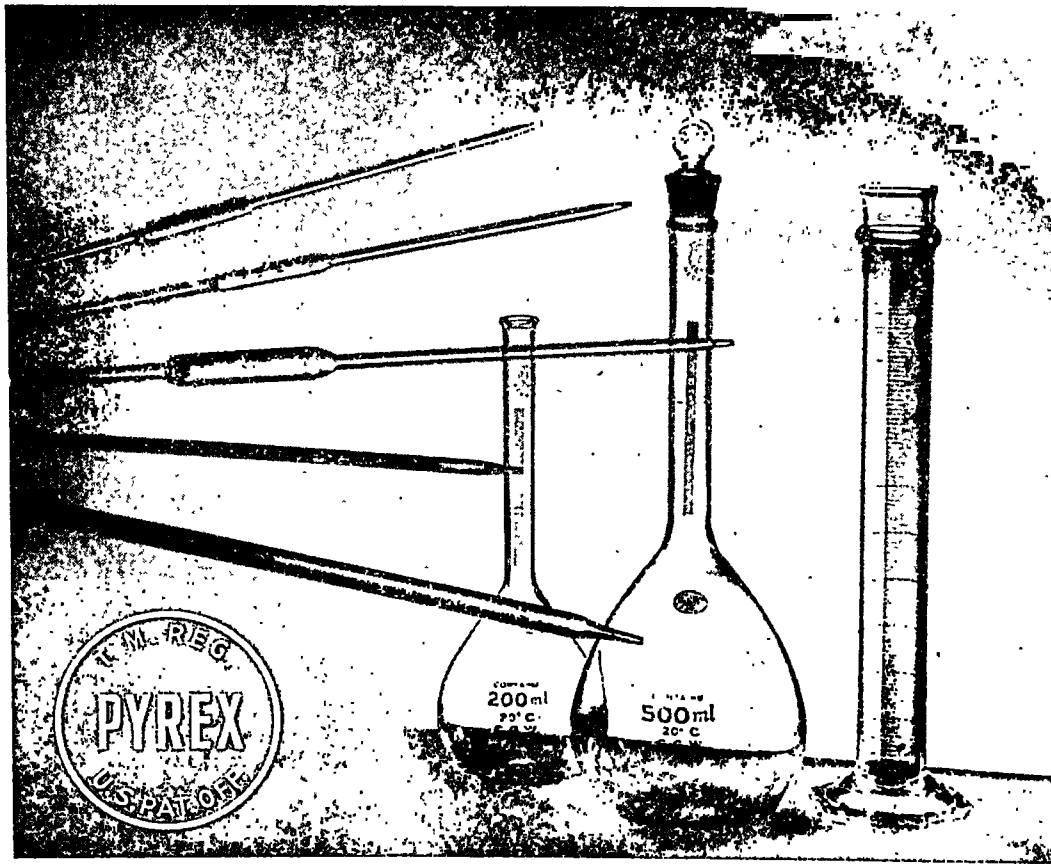
NO MESS...
NO GREASE...
NO SCABIES

You remember how just hearing that a certain patient had scabies or pediculosis would make you itch even if you never went near him. And you remember only too well the ointment-smeared bedding that seemed the only way to get rid of the pesky skin parasites.

Now all this is obsolete. With 'Wellcome' Benzyl Benzoate Emulsion, the patient is merely painted with a clean, *non-greasy* emulsion, and when he bathes twenty-four hours later, the parasites are dead. Recurrence and dermatitis are infrequent.

'WELLCOME' BRAND

BENZYL BENZOATE



EMULSION 50%

Diluted with an equal volume of water before application. 2 or 3 fluid ounces of the 25% emulsion is usually sufficient for one treatment.

The BIGGEST VALUE in VOLUMETRIC WARE!

Corning does many things to give you the biggest value in volumetric ware. Made of PYREX brand glass No. 774, it's tops in quality. This pays off in longer service life and in greater accuracy.

In its chemical stability and resistance to thermal and physical shock, PYREX volumetric ware is outstanding. You can use it for so many different applications that it gives you greater working flexibility.

The design of this ware is also unique. PYREX brand cylinders are made with hex bases. They can't roll. Some types are made with reinforced tops. This minimizes breakage from accidental tipping. Each piece is individually calibrated for accuracy. This all adds up to bigger value.

And, PYREX volumetric ware is available with or without "Lifetime Red" graduations. When you specify "Lifetime Red," you know that the graduations will be permanent and *always* can be read. So when you order volumetric ware from your Corning Laboratory Supplier, specify PYREX brand and get extra value.

With FLO-CILLIN "96" you can avoid the frequent injections that make some penicillin patients feel like pincushions. A single 1 cc. injection every 48 hours constitutes full penicillin dosage in all but exceptional cases. And this gives ample margin for safety, because this single injection of 1 cc. provides therapeutic blood levels for 96 hours in 90% of patients.

Free-flowing FLO-CILLIN "96" spares you many annoyances too. It is constantly fluid, needs no prolonged shaking, won't "settle out." Whether your syringe is wet or dry, it won't clog the needle. It saves your time in office and home treatment, and of course it saves valuable nursing time in the hospital.

You can obtain this remarkable new repository penicillin from your usual source of supply. In rubber-capped 10 cc. vials, and in 1 cc. cartridges for use with the B-D Disposable Cartridge Syringe and the B-D Metal Cartridge Syringe.

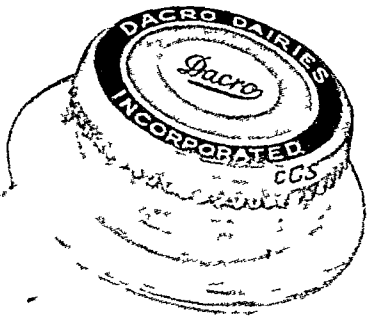
BROWN Blood Grouping and Cross Matching BOARD

- Minimizes the possibility of technical or clerical errors.
- Embodies all the latest approved technics of blood grouping, Rh typing, Rh sensitivity testing and cross matching for transfusion.
- Simplifies and combines these technics in an orderly sequence.
- Facilitates the grouping and cross matching of blood for emergency or routine use.
- Can be used for routine Rh typing and sensitivity testing in individual maternity cases.

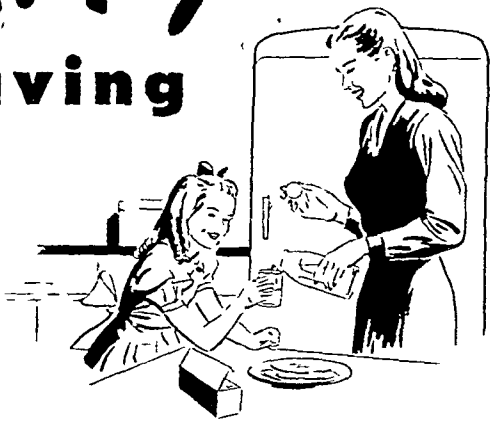
The Brown Board [1] was developed in the Duke University Hospital Blood Bank to increase efficiency and reduce errors in blood typing and cross matching. It consists of an etched and stamped metal plate on a hardwood base, with an Rh typing box, anti-serum bottle adapters, reagent bottles, test tubes, dropping pipettes and concavity slides for Rh typing.

Tubes and reagent bottles have in-the-glass labels in different colors, matching the labelling and coloring of their places in the board. Each reagent bottle and cross matching tube is of a different shape and size, so that it fits only in its proper place. Anti-serum bottle adapters hold any commercial anti-serum bottle; they are permanently marked, fit only in their own place in the Board and are colored to conform to the coloring recommended for the sera by the National Institute of Health. Reagent bottles and adapters are designed to permit one-hand removal and replacement of the dropping pipettes.



The Rh typing box [2] is lighted, tiltable and designed to maintain a temperature of 37° to 42° C in the slide concavity where the blood sample is placed.

The Board has a slot to hold the Donor Card and Transfusion Request Form directly in front of the technician while tests are being made. A blotting paper holder is also provided, conveniently near the technician.



1. "A Note on Blood Grouping and Cross Matching with Special Reference to a Convenient Cross Matching Board." Brown, I. W., Jr., M.D. In press.
2. "The Demonstration of Anti-Rh Agglutinins—An Accurate and Rapid Slide Test," Louis K. Diamond, M.D., Boston, Mass., and Neva M. Abelson, M.D., Philadelphia, Pa., Jl. of Laboratory and Clinical Medicine, Vol. 30, No. 3, March 1945.

A-2800 Brown Blood Board, complete with Rh typing box, anti-serum bottle adapters, reagent bottles, test tubes, dropping pipettes and four-concavity slides. Each $90.00

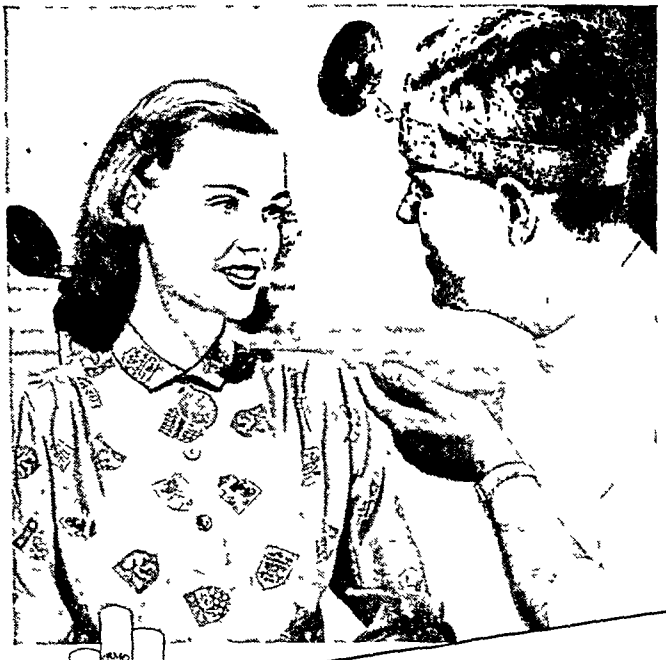
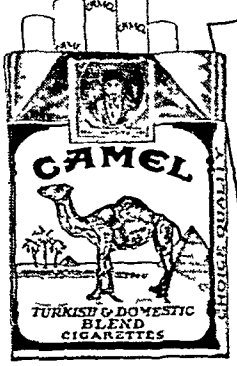
Prove CAMEL MILDNESS *for Yourself!*



Money-Back Guarantee!

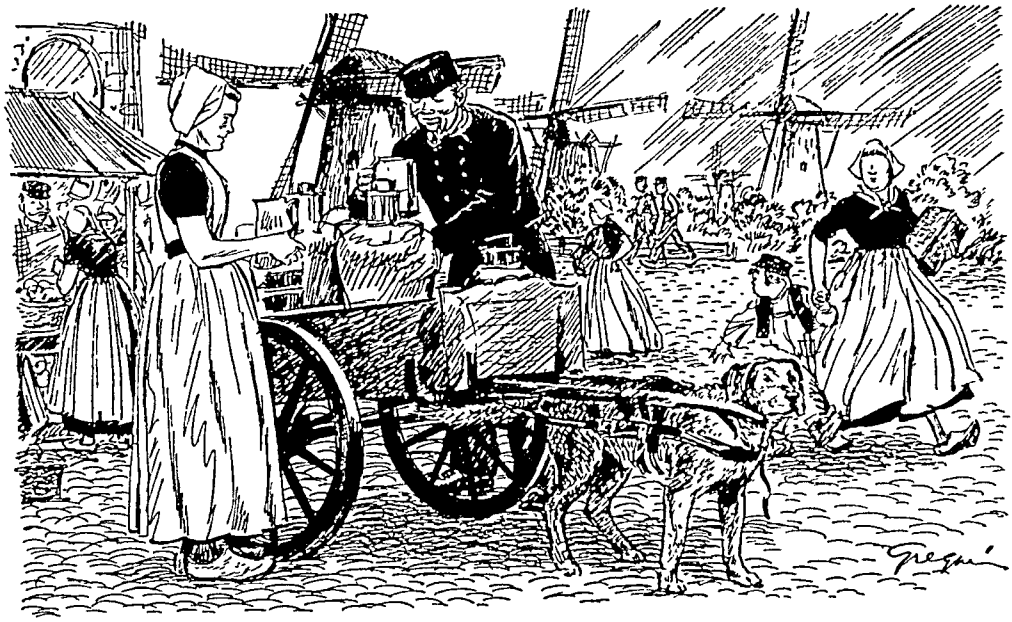


Test Camel Mildness for yourself in your own "T-Zone"—T for taste, T for throat. If, at any time, you are not convinced that Camels are the mildest cigarette you ever smoked, return the package with the unused Camels and we will refund its full purchase price, plus postage. (*Signed*) R. J. Reynolds Tobacco Company, Winston-Salem, North Carolina.

In a recent coast to coast test of hundreds of people who smoked only Camels for 30 days, throat specialists, after weekly examinations, reported:

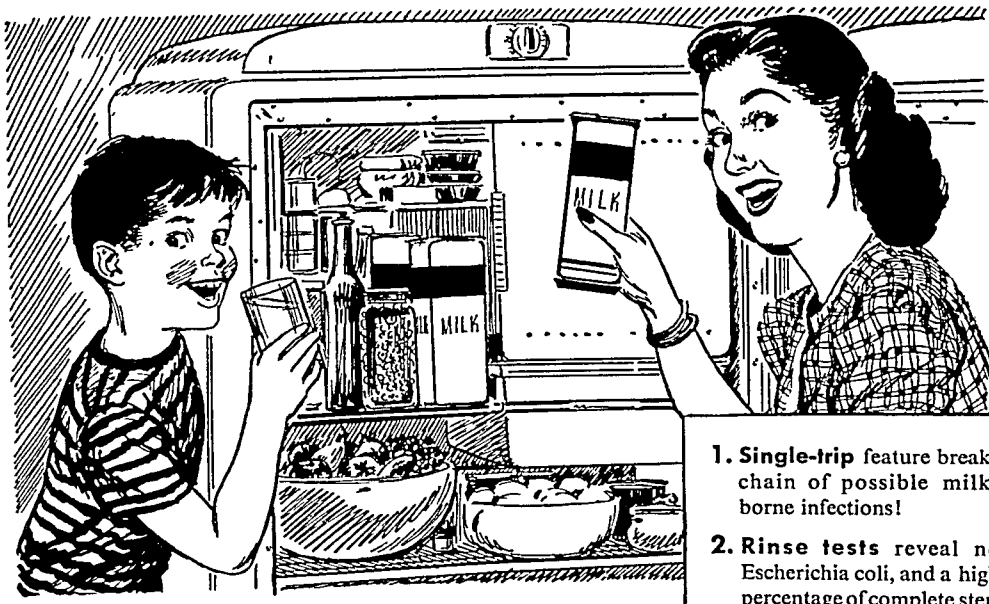
"Not one single case of throat irritation due to smoking CAMELS!"

Hundreds of men and women were included in this coast to coast test. These men and women smoked Camels—and only Camels—for 30 consecutive days. They smoked on the average of one to two packages a day. Each week noted throat specialists examined the throats of these Camel smokers—a total of 2470 careful examinations. In every report, the findings of these throat specialists were the same—"not one single case of throat irritation due to smoking Camels."



According to a Nationwide survey:

MORE DOCTORS SMOKE CAMELS



than any other cigarette

Doctors smoke for pleasure, too! And when three leading independent research organizations asked 113 597 doctors what cigarette they smoked the brand named most was Camel.

In Delft a well-fed hound draws a two-wheeled cart containing two large red copper cans. Measuring cans hang from the sides. This picturesque, two-way system is easily contaminated by germs causing milk-borne infections.

In America you'll find safe, sanitary Canco flat-top Paper Milk Containers . . . the one-way system whose nation-wide acceptance has been aided by Public Health officials.

1. **Single-trip** feature breaks chain of possible milk-borne infections!
2. **Rinse tests** reveal no Escherichia coli, and a high percentage of complete sterility in containers delivered to the dairy.
3. **Opened, filled,** and closed in minimum time by machines!

An Important Meal in Health...

Doubly Important in Convalescence

BREAKFAST skimping has no place in convalescence, since a poor morning meal may impose an impossible task on the other two meals in providing the daily nutrient needs.

A good starting point in planning breakfast for the convalescent is a widely acclaimed basic breakfast pattern consisting of fruit or fruit juice, cereal, milk, bread and butter. Other suitable foods may be added to bring the caloric and nutrient contributions to the desirable one-fourth to one-third of the day's nutrient requirements.

This pattern breakfast is rarely contraindicated. It is exceptionally well balanced as evidenced by the table of nutrient composition, and may be varied almost endlessly to provide renewed taste appeal. The cereal serving, consisting of breakfast cereal,* milk, and sugar, is an important component of this meal.

The presence of this seal indicates that all nutritional statements in this advertisement have been found acceptable by the Council on Foods and Nutrition of the American Medical Association.

Council Accepts Propion® Gel

Propionate compound jelly

A new treatment for mycotic vulvovaginitis (moniliasis). Propion Gel was developed to free physicians and patients from the disadvantages of the classical gentian violet method. It contains propionates and propionic acid . . . two highly effective anti-fungous agents.

Clinical reports show that Propion Gel usually produces symptomatic relief in three days or less . . . negative cultures after three weeks in many obstetric, in nearly all gynecologic, cases. Also that Propion Gel is innocuous, convenient, nonstaining.

As a result of this evidence, Propion Gel now stands accepted by the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in *New and Nonofficial Remedies*.

Literature on request. Propion Gel comes in 95-gram tubes (7-day supply)—with or without applicator. Wyeth, Philadelphia, Pa.

THE PLACE OF *Candy* IN THE *Balanced Diet*

In a carefully chosen, well balanced dietary providing all essential nutrients in proper amounts, there is adequate provision for foods which do more than merely satisfy nutrient needs—foods which are especially tempting to the palate. Candy is that kind of food.

Supplying valuable caloric food energy, it also imparts to a meal a finishing touch of which few other foods are capable. Candy, with its almost irresistible attraction, need not be denied children or adults providing the dietary is adequate in all other respects. In fact, candy at the conclusion of a meal imparts a feeling of satiety and a sense of having eaten well, both of which enhance the functioning of the digestive processes.

Many candies are made of valuable foods in addition to sugar—butter, milk, cream, eggs, nuts and peanuts—and to the extent these foods are present, candies contribute biologically adequate protein, vitamins, and minerals.

THE NUTRITIONAL PLATFORM OF CANDY

1. Candies in general supply high caloric value in small bulk.

2. Sugar supplied by candy requires little digestive effort to yield available energy.

3. Those candies, in the manufacture of which milk, butter, eggs, fruits, nuts, or peanuts are used, to this extent also—

(a) provide biologically adequate proteins and fats rich in the unsaturated fatty acids;

(b) present appreciable amounts of the important minerals calcium, phosphorus, and iron;

(c) contribute the niacin, and the small amounts of thiamine and riboflavin, contained in these ingredients.

4. Candies are of high satiety value; eaten after meals, they contribute to the sense of satisfaction and well-being a meal should bring; eaten in moderation between meals, they stave off hunger.

5. Candy is more than a mere source of nutriment—it is a morale builder, a contribution to the joy of living.

6. Candy is unique among all foods in that it shows relatively less tendency to undergo spoilage, chemical or bacterial.

Why Use Break-Point?

In answering the question "Why Use Break-Point", the chemist of a 2 MGD southern water plant gave as some of his reasons—

"Briefly, it eliminates odor and taste; it oxidizes iron and manganese; it removes color; it sterilizes the water; and keeps the filters and mains free from organic growth".

Wallace & Tiernan, pioneers in chlorination for over 35 years, lead the way in solving water treatment problems through the Break-Point Process in hundreds of installations across the country. They are ready to show you how Break-Point can help in your plant, too.

Call your nearest W&T Representative. He'll be glad to tell you, without obligation, how the Break-Point Process can be applied effectively in the solution of many of the operator's most trying problems.

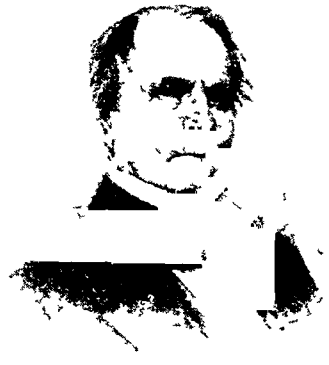
Lemuel Shattuck—Still a Prophet

Lemuel Shattuck — America's Great Public Health Pioneer *



W. G. SMILLIE, M.D., F.A.P.H.A.

Department of Public Health and Preventive Medicine, Cornell University Medical College, New York, N. Y.

WE are met to commemorate a centennial of public health progress in America, and to pay tribute to America's foremost public health pioneer. For it is now quite clear that the cornerstone of the splendid edifice of public health in this nation was laid in the City of Boston one hundred years ago, with the publication of the famous *Report of the Sanitary Commission.*

I am sure that many of you are asking, "Why should we be interested in, and dwell upon the past, with all its mistakes, its tragedies, and sordid miseries? Why not consider instead the triumphs of the present, and plan for an even more brilliant future?"

With full realization of the great value of thinking for, and in the future, I bespeak your attention, for a brief period only, to the value of retrospect. For a knowledge of the past not only enables us to determine present trends, but is of inestimable value in helping us plan intelligently for the future. The very nature of our work requires that we become immersed in details. Our vision becomes narrow; our concepts and our viewpoints tend to be tinged with arrogance, self-satisfaction, and impatience with the views of others. We have no true understanding of our function in the world, and no breadth of knowledge of social progress. There

LEMUEL SHATTUCK
1793–1859
From *Pioneers of Public Health,* M. E. M Walker, The Macmillan Company, 1930.

* Presented before the American Public Health Association at the Seventy sixth Annual Meeting in Boston, Mass., November 10, 1948

comes a time when we must pause, and go up to the mountaintop, to obtain complete detachment from our immediate tasks, and to look to the East whence we have come, and to the West, whither we are going.

In so doing, we gain a broader vision, and better understanding of our task. We gain also *humility,* for we soon realize that the original ideas that we thought out so painfully have been presented quite effectively many years ago. We gain *patience* and true perspective in the realization that social progress in a democracy is slow, proceeding arduously, step by step. Advances can never move faster than the social consciousness of the average man. We also gain *courage* and *hope* that some of our own ideas that we have fought for, and which have been completely defeated, will at some future time, and long after we are forgotten, emerge as an integral part of community service.

In this discussion we shall present only a small segment of time, and the activities of a single man. But these events serve to illustrate the broad and basic principles of public health progress, and will point to clear-cut analogies which show us the way to further gain. We shall show you also the place in human affairs of the seer, the prophet, the pioneer. We shall not present a leader, since the leader comes after the philosopher. The philosopher formulates his ideas far in advance of current thinking; thus he seldom lives to see realized even a single one of his concepts, no matter how fine and sound they may be. The leader who comes after must carry out the ideas, but he cannot get too far ahead of the people, else he loses his contact with them.

The pioneer has a lonely life. He is misunderstood, misinterpreted, sometimes persecuted, at best treated with friendly, but ill-disguised tolerance. All these things came to Shattuck. He was treated with scant courtesies by physicians, and laymen. His report was buried in the dusty archives of official documents, and he died long before even one of his fifty recommendations was accepted by the community.

My assigned task is to introduce to you the man, to present a brief outline of his life and achievements, and to paint with broad strokes the background of the period in which he lived.

Lemuel Shattuck was born in Ashby, Mass., in 1793,[1] and died in Boston in 1859. His parents were farmers. He had a very limited formal education, but through self-education he qualified himself as a school-teacher and went west to the frontier town of Detroit about 1818 to teach in the district schools. He became interested at once in community welfare.

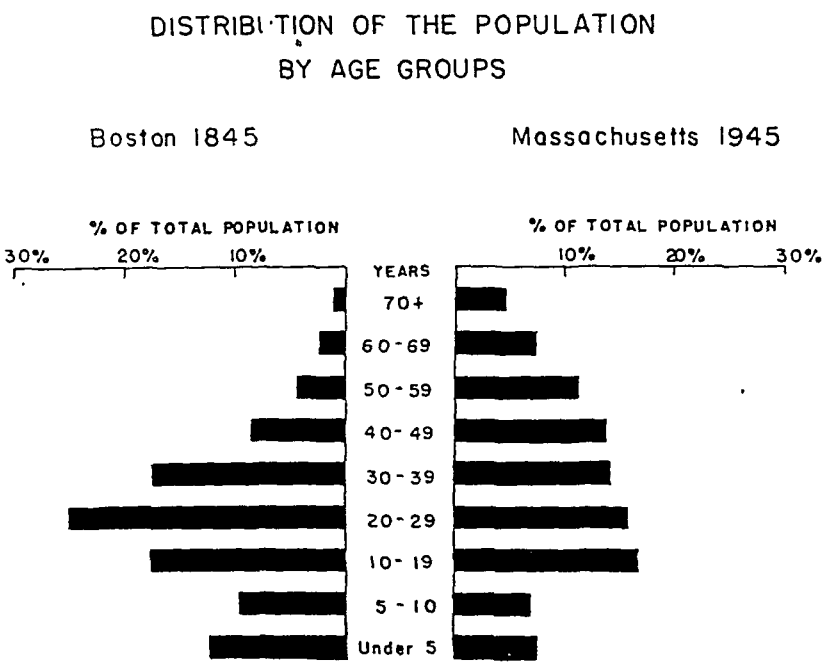
He organized there, in the wilds of that great wilderness, the first Sunday School in the State of Michigan, and was its superintendent for four years. He returned to the East, married, and settled in Concord. Here he ran a general store for some ten years.

As a member of the school committee in Concord, he reorganized the public school system of the town, and was active in the community affairs.

In 1833 he moved to Boston and entered the book publishing and book selling business. He became a member of the City Council and took an important part in the long controversy over the introduction of pure water into the city.

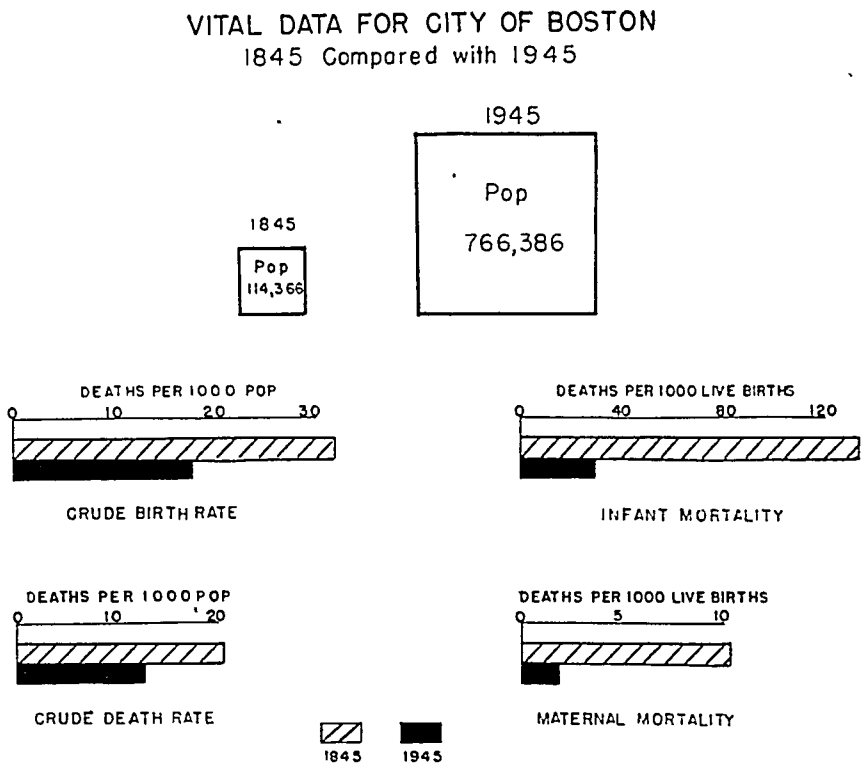
Shattuck's interest in vital statistics was aroused through his initial interest in genealogy. He attempted to collect accurate data for the history of his own family, and he also wrote, in 1835, a *History of the Town of Concord.* Finding great confusion and inadequacy in the church records of births and deaths, he began a personal and almost solitary campaign to obtain the official recording of vital data. In 1842 he was successful in securing the passage of an act for a

registration system of vital statistics for Massachusetts, which became a model for all other states. Since there was no State Board of Health, the Act provided that the returns should be made to the Secretary of State. This plan remained in effect in Massachusetts for over one hundred years.



The *Report* of the "Census of the City of Boston"[2] in 1845 was a precursor of his more famous report of 1850, but in many ways it is equally important, for, in it, one can obtain a very clear picture of the economic and social conditions of that day.

The nation was in a period of vigorous growth. James Polk was President from 1845 to 1849. His diary[3] emphasized the following important events during his term:



1. The termination of the war with Mexico and acquisition of California and the Southwest
2. The annexation of Texas
3. The settlement of the Oregon boundary
4. The increase of national feeling concerning the whole question of slavery

During his term, gold was discovered in California, and the great migration to the far West began.

Immigration[4] from Europe was at flood tide. From 1790 to 1810; some six thousand persons came to America each year from Europe, but this flow was completely stopped by the war with Britain in 1812. Laws regulating immigration were passed in 1819, but during the subsequent ten years only 150,000 persons entered The States. Then came the political persecutions in Germany and the potato famine in Ireland. These initiated the avalanche. Over four million persons came from Europe to America from 1819 to 1855. Of these, 1,700,000 were Irish, and 1,200,000 were Germans. In 1848 alone, 230,000 entered our borders. The peak was

GRAPH I—*Distribution of the Population by Age Groups.* This graph shows preponderance of the younger age groups in the population a century ago. Data for 1845 from Lemuel Shattuck's Census of Boston. Data for 1945 from the Massachusetts State Board of Health's Annual Report.

GRAPH II—*Vital Data for City of Boston.* The vital data for 1845 were obtained from Lemuel Shattuck's Census of Boston; 1945 data were secured from Boston's Health in 1945, official report of the Boston City Health Department.

reached in 1854 with a total of 400,000. Males outnumbered females 2 to 1. More than half of the immigrants were between 15 and 30 years of age. Laborers made up the largest quota, with very few skilled workers, and almost no professionally trained people.

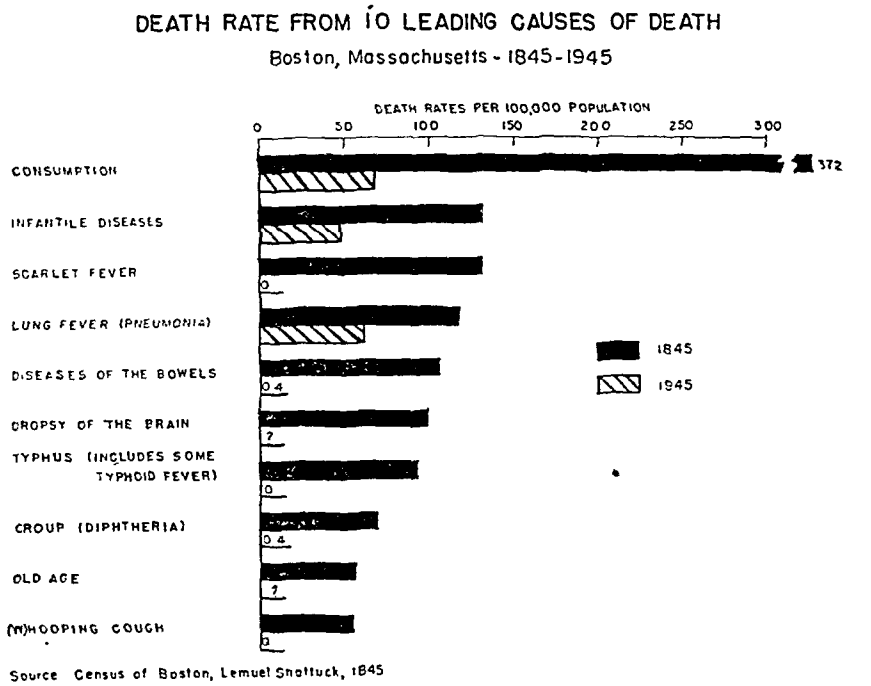
Industrialization of the Atlantic Seaboard had begun, and the textile factories of New England absorbed large numbers of these immigrants. There were no child labor laws. Children went to work in the factories at 8 years of age, and the working day was 12 hours or more.

Housing laws were nonexistent. There were no departments of health; when epidemics occurred, a special board of physicians was selected to deal with the immediate situation. Isolation, quarantine, and even the reporting of communicable disease was opposed because "(a) these regulations interfered with private rights, and (b) they were injurious to business." It was generally held that a disease such as scarlet fever, which was highly prevalent and severe, "occurs under no fixed laws, and seems inclined to abide with us."

The nation was young, vigorous, boisterous, callous, exuberant, with all the virtues and all the faults of a gangling adolescent, who has outgrown his clothes, broken away from his parents, and has awkwardly tried out his strength. He is uncertain and insecure, but bursting to demonstrate his great importance to the whole world.

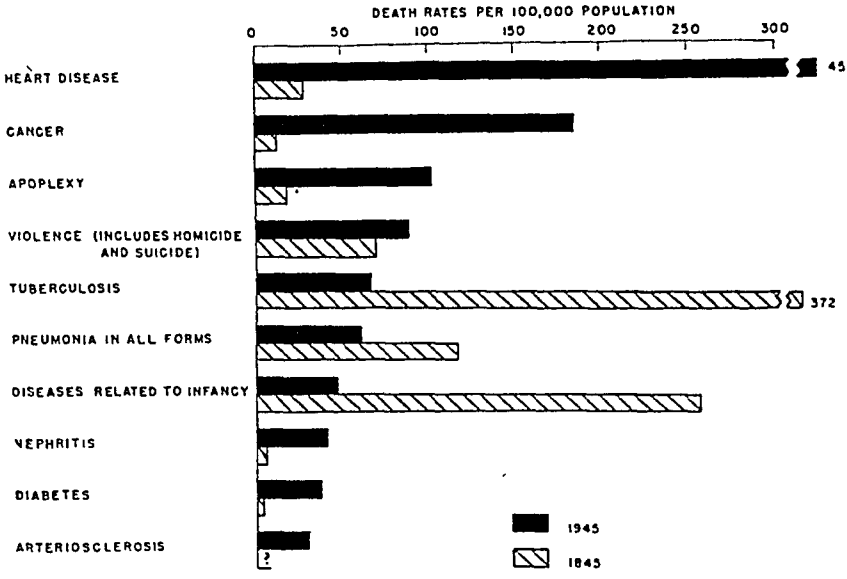
Massachusetts was one of the more conservative and settled sections of the nation, but foremost in the coming industrial revolution. It must also be remembered that it was largely New England men who gave the impetus and

leadership to the western expansion.



As I have said, the Shattuck *Report* of 1845 on "Census of the City of Boston" gives us an accurate picture of the mode of life and the state of civilization in the nation as a whole.

From the *Report* of 1845, we have compiled certain simple vital data which are comparable with similar data for the Boston of 1945, just a century later.



The city has grown sevenfold. The distribution by age groups of the population in 1845 and 1945 is shown in Graph I. The graph shows that the city, once composed of young, vigorous men, is now staid, and well past middle age. The Boston of 1845 was not only made up of young people, but they had large families. Males greatly outnumbered females; most of these young men were recent immigrants from Ireland. The birth rate was very high (see Graph II), with a correspondingly high death rate and a shocking infant mortality rate. The maternal mortality rate was a tragedy. In the slums of the city, Shattuck says the birth rate was over 60 per 1,000 population, and the infant death rate was estimated to be between 300 and 400. In the immigrant section, he estimates that one mother in 37 died from childbirth.

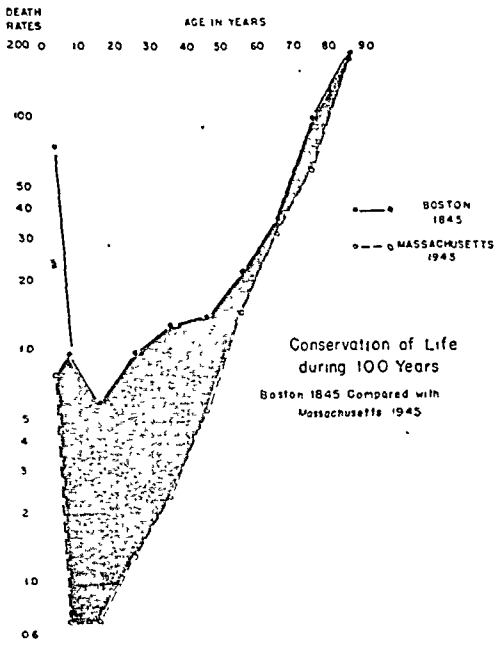
We have tabulated the important causes of death in 1845 and, in so far as possible, have compared them with similar causes of death in Boston in 1945 (see Graph III). The striking features of this chart are:

1. The high prevalence of communicable diseases
2. The heavy toll in 1845 of tuberculosis
3. The seriousness of scarlet fever
4. The absence of degenerative diseases as leading causes of death

GRAPH III—*Death Rate from 10 Leading Causes of Death, Boston Massachusetts 1845–1945.* This graph shows an almost entire disappearance in 1945 of the important causes of death 100 years ago. Data from Census of Boston, Lemuel Shattuck, 1845; and Annual Report of Massachusetts State Board of Health, 1945.

GRAPH IV—*Death Rate from 10 Leading Causes of Death, Boston, Massachusetts 1945–1845.* This companion graph to Graph III shows that degenerative diseases have replaced communicable diseases as important causes of death after a 100 year period. Only tuberculosis, pneumonia, and diseases related to infancy are still in the first ten causes. Comparisons in Graphs III and IV are not completely reliable, since the terminology has changed during the past 100 years.

The terminology of 1845 is somewhat obscure. The term "diseases of the bowels" includes for the most part typhoid fever and bacillary dysentery, but excludes inflammation of the bowels (appendicitis).



Dropsy of the brain or hydrocephalus, which is given as an important cause of death, is described by Thatcher[5] as "a very serious disease of childhood, commencing suddenly, and terminating fatally in a very few days. Such is the ambiguity of its symptoms that it is difficult to determine what are its real characteristics. The indisposition of the child is sometimes attributed to teething or to a disordered state of the bowels. Frequently it resembles the common febrile complaints of childhood."

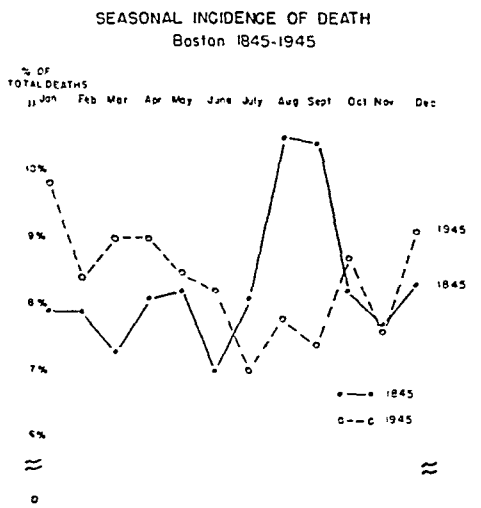
This disease dropped out of the nomenclature within a few years. It was like the "Hives," which was frequently given as a cause of illness even in the last generation. If the child had a fever with rash, it was the "Hives," without a rash, it was "Inward Hives." If the child died, it had "the Bold Hives."

In Graph IV we have compared the common causes of death in Boston in 1945 with similar causes of death in 1845. The graph speaks for itself.

The degenerative diseases have almost completely replaced the contagious diseases as important causes of death. A comparison of 2045 with 1945 will be equally interesting.

In Graph V we have presented a summary of deaths in 1845 by age groups and compared these rates with 1945. The data for 1845 are from Boston; those of 1945 are from the whole State of Massachusetts. The rates are determined for each 1,000 of the popula-

GRAPH V—*Conservation of Life during a 100-year Period.* This semilogarithmic graph indicates that the proportionate conservation of life in Boston has been greatest in the early decades, but continues throughout life. Sources: Census of Boston, Lemuel Shattuck, 1845. Annual Report of the State Board of Health, Massachusetts, 1945.



tion within that age group. The graph may be entitled "Conservation of Life." It shows clearly that the saving of life has not been limited to infants and school children but extends throughout the life span. Only in the seventh and eighth decade of life does the death rate correspond in 1945 to that of a century ago. How interesting it will be to make a comparison of this type in 2045.

We have also made a comparison of deaths in 1845, by months, with similar data for 1945 (Graph VI). In the last century, the summer months were most dreaded, and winter was by far the most healthy period. A hundred years later this picture is exactly reversed.

From these simple comparative data, it is quite clear that the great public health need in Boston a century ago was a well organized, effective community plan for control of communicable disease.

As already noted, Mr. Shattuck had appreciated the primary importance of pure water, and had been active in the City Council for ten years in securing a municipally owned adequate water supply to be piped from Framingham. It required a period of ten years to consummate this plan (1848).[6]

Boston was in advance of other communities also in diverse aspects of environmental sanitation. In 1848, the great cholera epidemic began. The infection came from Europe, and spread south and west to devastate the whole nation. The Boston City Council forthwith organized itself as a Board of Health. Every policeman was made a sanitary inspector, and the town had such a thorough house-cleaning as it had never experienced. Streets and alleys were scrubbed, rubbish was burned, and privy vaults were emptied. Cholera came, but did not obtain a firm foothold. The pest house opened June

GRAPH VI—*Seasonal Incidence of Death.* This graph shows the monthly percentages of total deaths in Boston for 1845 and 1945. The graphs are exactly reversed in that in 1845 the winter was a period of low death rate, August and September showed the highest death rates; in 1945 the lowest death rates are now in the summer.

29, and could be closed on November 15, with only 262 admissions, of whom 166 had died.[7]

The physicians of the community were not interested in preventive medicine, but confined themselves to the treatment of disease. Doctors were numerous. In the classification of occupations in Shattuck's Census of 1845, there were 680 persons in the city of 114,000 population whose occupation "contributed to health." This list included, of course, some auxiliary professions, such as sextons, undertakers, botanic medicine dealers, leechers (15—all women), and one electrician. But there were 236 *bona fide* doctors, 169 druggists, and 57 dentists. Ninety women were classified as nurses, all of course with practical training only. Ten of the doctors were women. Thus, the medical profession, in proportion to the population, outnumbered the physicians of Boston today. But what doctors!

It must be remembered that there were few restrictions on medical practice. Physicians were trained by studying with another doctor as praeceptor. Formal medical training consisted of a four months' course of lectures. With a few exceptions, the medical colleges were not under university auspices. A few leading doctors in any community would simply organize a medical school, give a series of lectures, and divide the fees. The American Medical Association was founded in 1847. Its original purpose was, primarily, to raise the educational and ethical standards of the medical profession, and to curb, in some degree, the disgraceful practices of badly trained, grossly unqualified physicians.

Medical[8] research in all of America was practically nonexistent. The American Association for the Advancement of Science was founded in 1848 and is celebrating its centennial this year. But it was made up largely of geologists, with almost no physicians in its membership. (It is true that John Collins Warren, a surgeon of Boston, in 1837 attended a meeting of the recently founded British Association for the Advancement of Science in London and, on his return, agitated for a similar society in America, but to no avail.)

GRAPH VII—*Death Rates in Boston.* Comparison of death rates in Boston over a period of three centuries. The data for the 18th century are taken from church records and are probably underestimated. The 19th century data are from Shattuck's Census of Boston, 1845; 20th century data are from Boston's Health in 1945, 74th Annual Report of City Health Department. The striking feature of this graph is the extraordinary high death rate of the pioneer period.

Shryock[9] states that in 1840, "Medical research had not permeated even the best medical centers. The schools remained didactic, clinical teaching barely existed, and pathological investigation was sporadic." Samuel Jackson, commenting favorably upon the inten-

sive medical research in Germany, added indignantly, "not one man is now conducting similar studies in the United States."

Oliver Wendell Holmes[10] published his essay *The Contagiousness of Puerperal Fever* in 1843, but his observations fell on sterile ground. Epidemiological concepts were fragmentary and most inaccurate. The difficulty was that the theory of contagion did not explain the fact that diseases such as plague, cholera, typhoid, and yellow fever frequently were not transmitted following direct contact, whereas cases of these infections often arose with no demonstrable contact with another case of the disease.

Furthermore, scientific research was not fashionable. The commercial spirit pervaded the whole nation. Money was the goal of every man. It was the only criterion of success. The physician's only means of support was clinical practice, and there was little or no prestige in research. Those who might engage in clinical investigation as a primary pursuit were regarded by their fellows with scorn and suspicion, or at best, as hair-brained eccentrics.

The average income of physicians was estimated in 1845 to be about $800 per annum, of which $600 was net profit. But a dollar in 1845 had greater purchasing power than a century later.

Jarvis,[11] a physician, wrote a series of articles in the *Atlantic Monthly* in 1869 on the "Increase in Human Life." He pointed out that a good mechanic in 1821 worked a full day to earn the equivalent of a bushel of wheat; whereas in 1861, he could earn a bushel of wheat in one-half day. By 1948, a skilled artisan can earn the equivalent of a bushel of wheat in about 48 minutes of an 8 hour day. Thus in 1848 as in 1948, the wages per hour of a skilled laborer are greater than the hourly rate of average annual income of a practising physician.

Hospitals were for the poor. The Boston Dispensary had served for many years as a public clinic for the sick poor, and the Massachusetts General Hospital, in 1848 as in 1948, was one of the leading philanthropic hospitals of the nation. The concept was just emerging that the community was directly responsible for providing a municipal hospital for care of the sick poor, and a proposal had been advanced for establishment of the present Boston City Hospital. Treatment of mental disease had not been widely recognized as an official state responsibility.

In brief, the City of Boston in 1845, representing the more cultured portions of the United States had no concept of community responsibility for the promotion of the public health. There was no local or state department of health. Communicable disease took an enormous toll, particularly in the early decades of life. There was no real understanding of the epidemiology of infectious diseases, and methods of control were primitive and ineffectual. Official registration of vital data had just been introduced, but reporting of contagion was not established. Physicians were poorly trained, with no interest whatever in public health or preventive medicine. Medical research, in fact all scientific research, was nonexistent. Some attempts were made to provide for the general sanitation of the city under official auspices, but the relation of the basic factors in environmental sanitation to prevention of illness was poorly understood.

It was in this completely inhospitable environment that Shattuck compiled his report in 1850. He was actively opposed by physicians, as well as by his peers in the legislature. Bowditch notes[12] (in 1876), "I remember Mr. Shattuck well. Calm in his perfect confidence in the future of preventive medicine to check disease, he walked almost alone the streets of his (native) city,

not only unsustained by the medical profession but considered by most of them an offense for his earnest advocacy of what seemed to the majority of physicians to be out of a layman's sphere, and withal of trifling moment, compared with the importance of our usual routine of practice. The public, ignorant of hygiene, treated him no better."

One can readily discern the source of Shattuck's stimulus. He was an omnivorous reader, and his interest in vital statistics led him inevitably to study the pioneer activities of another layman, Chadwick of London, the founder of sanitary science in England. Chadwick published his famous report on *The Sanitary Conditions of the Laboring Classes of Great Britain* in 1842. Shattuck was familiar also with the work of the great British vital statistician, William Farr, and drew many of his ideas and much of his inspiration from Thomas Southwood Smith and from John Simon. The list of books which Shattuck recommends for sanitary libraries and which is appended to the 1850 report, shows clearly that he was quite familiar with the advances in sanitary knowledge that had occurred during the recent years in Europe, and particularly in France, Germany, and England. From these sources of information and methods of procedure, he drew the inspiration to write the *Report of the Sanitary Commission.*

He secured the assignment to write this report by devious measures. Shattuck in 1847 was a member of the Boston City Council and had been selected to represent the city in the State Legislature. The American Statistical Association, of which Shattuck was a member, suggested to the State of Massachusetts in 1848 that a "Sanitary Commission" be appointed, "to prepare and report to the next General Court a plan for a sanitary survey of the state, embracing a statement of such fact and suggestions as they think proper." This wording is, fairly obviously, Shattuck's own. The proposal was accepted, and a Commission of three appointed by the Governor: one Whig, one Democrat, and one Free Soiler. They were Lemuel Shattuck of Boston, Nathanial P. Banks of Waltham, and Jehiel Abbott of Westfield. Mr. Shattuck was chairman. One can be quite certain that Mr. Shattuck arranged for the original suggestion, engineered the committee appointment, and had his outline of the survey all prepared and the *Report* partially written long before authorization was secured. Of Mr. Banks and Mr. Abbott we know little, either before or after the report was written. Apparently, they played no part whatever in the organization or formulation of the survey, though they are listed as joint authors and are, in theory at least, equally responsible with Shattuck for the ideas that it contains.

This is the setting and these are the events that led to the writing of the Shattuck *Report*. My colleagues on this symposium will now interpret the report to you.

Lemuel Shattuck—Still a Prophet

Sanitation of Yesterday — But What of Tomorrow? *

ABEL WOLMAN, DR.ENG., F.A.P.H.A.

Professor of Sanitary Engineering, The Johns Hopkins University, Baltimore, Md.

NOT quite 100 years ago the Governor of the Commonwealth of Massachusetts was authorized to appoint three persons to prepare and report a plan for a sanitary survey of the state. The distinguished Bostonian, Lemuel Shattuck, with two associates, Nathaniel P. Banks, Jr., and Jehiel Abbott, prepared such a document covering an examination or survey of the different parts of the Commonwealth "in order to ascertain the causes which favorably or unfavorably affect the health of its inhabitants."

The Commonwealth was fortunate in the choice of Lemuel Shattuck as the chairman of the group. On the submission of the report on April 25, 1850, there emerged one of the most statesmanlike and significant contributions to sanitary science within the last century. The report demonstrated a vision and an imagination rarely surpassed in documentary public health material. It covered the wide range of physical impacts which have confronted man from the beginning of history. It included a number of items which even today continue to constitute part of the major stresses under which man still lives. It listed cogent reasons for sustained public interest in and control of nuisances, the atmosphere, water supply, and sewerage, buildings, housing, stream pollution, salt water travel, tenements, refuse collection and disposal, smoke, public health education, and innumerable additional philosophical and administrative aspects of preventive medicine.

Viewed in retrospect, the wide coverage of the report is impressive but not surprising, inasmuch as it reflected the comprehensive interests, particularly of the chairman of the Commission. Most people are perhaps still unaware that Shattuck was a member of the Common Council of Boston and as early as 1838 initiated the first resolution for the creation of a major water supply for the City of Boston. He combined in himself, therefore, not only the imagination and vision required for anticipating the necessities of the future, but had also an equally keen awareness of the necessity for preparing the way for acceptance of these ideas by the public and by the profession.

THE CENTURY'S ACCOMPLISHMENTS

In the light of this marvelous charter for public health action in the State of Massachusetts, what happened in the intervening century since its presentation? And, more important, what of tomorrow's objectives?

The record of the past is excellent, but unbalanced and incomplete. During

* Presented before the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

the past 100 years, professional groups were unanimously agreed that a safe and healthy environment for everyone was a prerequisite to most other activities aimed at preserving and improving the public health. And much was accomplished under this banner. It would be fruitless to enumerate statistically all of the details of these accomplishments. That they were significant only a few selected observations will demonstrate.

As late as 1900 there were only 3,200 public water supplies in the entire United States, purification plants were few, the quality of the water was generally poor and the death rates from water-borne diseases were high. Today some 85 million people are supplied with water through some 14,000 systems, providing a generally excellent quality.

The death rates from the filth-borne diseases, such as typhoid fever, dysentery and diarrhea-enteritis, have dropped to insignificant figures. A half century ago 23,000 people died of typhoid fever in this country and 100,000 died from diarrhea-enteritis and the dysenteries. In 1944 the deaths from typhoid fever were less than 600 and from the other enteric diseases approximately 15,000.

The situation in regard to the removal of sewage from built up communities has shown a similar improvement. Sewerage systems were available to only 25 million people in 1900, with only 60 sewage treatment plants serving about 1,000,000 people. Today more than 70,000,000 people are served by sewerage systems, and more than 5,500 treatment plants have been installed. These serve about 42,000,000 people.

In the field of milk pasteurization, not a single first class commercial plant was in operation 50 years ago, and today more than 70 per cent of our market milk supply is pasteurized.

WHAT OF TOMORROW?

Measured by these indices the accomplishment is good. A more realistic view of the future, however, discloses no overwhelming basis for basking in the glory of the past. When we ask what of the future in the control of the environment, we do so in the fond hope that the future may hold simpler and fewer tasks, more refined efforts, and even diversions of major character toward new and unexplored fields. The interested worker in sanitation might hopefully turn to the future with the assumption that his task was accomplished, except that the record of familiar things yet to be done is disconcertingly staggering. The evaluation of the prospects of the future must necessarily be made upon a broader base than that of the State of Massachusetts, even though that state alone gives many of the indices of future conquest which may be paralleled in the rest of the United States and may be multiplied a thousandfold in many parts of the rest of the world. It is curious that, when we look to the future, we rediscover the essential elements of program in the Shattuck survey of the past. What are the things that remain to be done and what are the additional objectives in sanitation?

WATER SUPPLY AND WASTE DISPOSAL

In the State of Massachusetts, as in the rest of the United States, it is doubtful whether there is a single stream today which has not deteriorated in a major sense in its quality since 1849. There is hardly a city in Massachusetts, or one in the rest of the United States, in which the conditions of housing are not essentially worse than those at which the Shattuck report directed severe criticism. There is not a city in Massachusetts or one in the rest of the United States, with pathetically few exceptions, in which the conditions of the atmosphere are not immeasurably worse today than they were when Mr. Shattuck leveled his attack on this phase of the environment.

On January 15, 1872, the famous artist and explorer, F. S. Dellenbaugh, recorded in his diary on the exploration of the Colorado River[1] that "The frontier town was a ghastly hodge podge of shacks in the midst of a sea of refuse." In 1948 several of my young friends canoeing down the Connecticut River recorded the same phrases in their diary, and I hasten to add that the same could be said about a number of other major streams.

Although somewhat over $10,000,000,000 have already been spent in this country for water supply and waste disposal facilities, a recent review[2] of the additional sanitation facilities required in these fields in 1947 shows them still in excess of $8,000,000,000. There are still almost 6,000 communities in this country with no public water works system. There are over 9,000 communities which need sewerage systems. In rural areas more than 33,000,000 people lack satisfactory sewage or excreta disposal facilities of even the simplest types. Some 70,000,000 people in 8,300 communities need modern facilities for collecting and disposing of garbage and other municipal refuse.

Houses have been built in the last 10 years with inadequate sanitary facilities which promise to become the slums of tomorrow, and of a not too distant tomorrow. The rural areas of this country have so far been beyond the reach of the practicable community facilities. In these areas the greatest shortages of sanitation facilities exist. And not all of these difficulties are attributable to the lack of money. They wait for solution for a Lemuel Shattuck to dramatize the necessities and, more important, to emphasize the practical engineering economic answers.

HOUSING

In 1947, there were approximately 41,625,000 dwelling units in the United States. In the urban areas over 5,000,000 of these, or 22 per cent, needed major repairs or lacked a private bath and toilet. About the same ratio of inadequacy prevailed in the New England States. In 1947, in the South, over 80 per cent of all the rural farmhouses were without running water. Only 20 per cent of the farmhouses in the entire country in 1947 had both bath and toilet facilities. Sixty-seven per cent of these farmhouses lacked running water within the house. Some improvement has occurred between the period 1940 and 1947, because in this period the figure of dwelling units for the entire country provided with private bath and toilet increased from 55 to 66 per cent, while the number of houses without running water declined from 30 to 22 per cent of the total.

A glance at any of the special problems in the field of housing and of sanitation presents even a more gloomy picture. *A Medical Survey of the Bituminous Coal Industries** made in 1947 is an example of this gloomy picture, best summarized in the following words from the report thereon (page 20):

> Although the world of today is one of nuclear fission and jet propulsion, of international aviation and frequency modulation, of frozen foods and penicillin, the simple bathtub or shower is still a rare item in the houses miners and their families occupy in coal-mining camps. Of the 1,154 company-owned houses inspected, only 121 contained bathrooms in which there were either tubs or showers, or both. . . . In privately owned houses occupied by miners and their families, 31 per cent had bathrooms with tubs or showers or both.

In these same areas privies are still the most common method of disposal in both company-owned or controlled communities and in other communities.

The report makes a further pertinent comment, which might be appropriately

---

* Supt. of Documents, Gov. Ptg. Office, Washington, D. C. Price, $1.75.

applied to other situations than the coal mining camp. The comment is as follows:

> The issue is not one of raising or lowering the standard of the miners to the levels of white collar workers or cotton pickers or any other vocational group. Rather, this study has been grounded on the premise that, all comparisons to one side, coal miners should share as much as possible in the dividends of good living sought by all Americans. It is granted that the deficiencies described are not unique if a similar survey were conducted among share croppers or itinerant harvesters. It is not unlikely that some conditions would be discovered so deplorable as to make those described herein seem rosy by comparison. In the very capital of the United States, approximately 100,000 persons [3] still draw their drinking water from yard hydrants and rely upon privies. Yet the lesson to be derived is not that the nation can well afford, therefore, to take time to ameliorate the condition of the miners, but that assistance should and must be extended to all citizens whose living conditions dispute the complacent assumption that man has attained the peak of progress.

MILK PRODUCTS AND FOOD

In the last 10 years almost 2,500 disease outbreaks have occurred from milk products and other foods, accounting for some 100,000 cases. The sanitary methods of producing, handling, preparing, storing, display and serving of foods offer almost an unexplored field for the professional worker in sanitation. Perhaps no small part of this activity presents a problem in public health education, although engineering ingenuity and research are required for the development of adequate facilities in food processing and handling establishments, as well as in the home.

Some 500 American communities now require the pasteurization of their milk, but there are still far too many communities, particularly the smaller ones, where pasteurized milk is unavailable.

INSECTS AND RODENTS

Even with the development of the miracle insecticides and rodenticides, such as DDT and "1080," most professional judgment is agreed that a more basic job of the elimination of man-made breeding places of insects and rodents must be done if the full effect of fly and insect control on diseases in general is to be accomplished. The insecticides and rodenticides developed in the past few years will bring about many accomplishments on a more economical basis than has hitherto been possible. The important fact remains, however, that no substitute for sound municipal housekeeping has yet been discovered, no matter how high our enthusiasms may rise for such substitutes, in the first flush of excitement at new and helpful discoveries.

On a world-wide basis, the suppression of the pestilential diseases is hardly imaginable without the existence throughout the world of satisfactory sanitation, and without the complete suppression of the important vectors of plague, yellow fever, typhus, and malaria. It is still true that, while many parts of the world are effectively protected against certain diseases such as cholera, little or nothing has been done to attack the endemic foci.

Throughout a large portion of the globe, millions of deaths and hundreds of millions of cases of malaria still occur annually. This disease alone has more impact than almost any other factor on the working capacity of populations and on the production of food. The economic consequences of this disease are immeasurably great. Insecticides now make it possible to contemplate effective malaria control in many malarious countries. The discovery of DDT-resistant strains of house flies has given rise to some alarm that some anophelines may be or may become similarly resistant. The work in Pakistan, in Sardinia, and in Cyprus will offer opportunities for evaluation of the varying procedures. The future still holds a major challenge for the profes-

sional worker in this field of sanitation.

ATMOSPHERE

Mention has already been made of the slow progress in the control of pollution of the atmosphere. Shattuck emphasized the significance of this field of activity, in the following terms (page 143): "We recommend that provision be made for obtaining observations of atmospheric phenomena, or a systematic and uniform plan at different stations in the Commonwealth." And on page 147, "It opens a vast field for examination, which is as yet almost entirely unexplored; but it promises results of great value and importance to science and to human life." It is pertinent to point out that our understanding of the effects of atmosphere upon the human population is not much better advanced than it was in Shattuck's day. The deaths in the Meuse Valley of Belgium in 1930 and in Donora, Pennsylvania, in the last 10 days are simple reminders, more dramatic than the smog of Los Angeles, that we still live in a world in which the missing physiological links between contaminated atmosphere and human reaction are many and subtle. Did these people die because of the phenomena and if so, why?—are important questions to be answered!

The industrial chemical operations which take place in a highly complex world such as ours, the number of which now exceeds 20,000, have never been completely evaluated in relation either to internal or external atmospheres. McCord has properly pointed out that we never catch up with the impact of industrial wastes to get ahead of them.

This is strikingly exemplified in the recent decision of the National Cancer Institute to create an environmental cancer section to undertake one of the first intensive surveys of man's environment with particular reference to carcinogenic circumstances, occupation, diet, climate, parasitic infections, etc. The environmentalist has much ahead of him with respect to this particular group of diseases, in which so many characteristics parallel those of the more familiar infectious diseases.

ACCIDENTS

One more area of future activity should be mentioned. It is not included merely to exhaust the list, because many additional aspects of environmental control have not been covered in this discussion. In 1947 some 101,000 deaths occurred in the United States from accidents. The 100,000 mark has been exceeded only four times before in the history of this country, 1934, 1936, 1937, and 1941. It has always been a considerable mystery as to why health departments have given little or no attention to these major causes of death. It is well to remind ourselves that here is one of the great killers of the modern age. It is therefore gratifying to record that in the 1947 report of the special commission to study and investigate certain public health matters in Massachusetts, emphasis is placed upon the death rate from accidents. Motor vehicle accidents alone caused 32,500 deaths in 1947. Official health department contribution in general to the amelioration of this particular area of mortality hitherto has been largely one of rationalizing itself out of any responsibility, an intellectual contribution hardly in consonance with the normal preambles to public health appraisal sheets.

Even though the risk of prophecy is great, one thing is certain for the future, that in the field of the control of environment, more remains to be done in the next century than has been done in the previous one. The Shattack charter, with minor adjustments in language, is an excellent charter for the next 100 years. In sanitation, great strides have been made in the last century, but the

correctives, in number, in kind and in effect have never caught up with the actualities. It still remains true, and I suspect that it will continue to remain true forever, that a sanitary environment for everyone, in Massachusetts, in the United States and in the world, in the words of Shattuck, "is attainable but is rarely attained." This work must go on and, in carrying it on, we must rely on the same three fronts of education, research and practice.

Local Public Health Services Bill Reintroduced

The Local Public Health Services Bill was introduced into the U. S. Senate on January 17. The bill is substantially in the form reported out favorably by the House Committee on Interstate and Foreign Commerce of the 80th Congress. Known as the Local Health Units Act, S 522, it was introduced on a bipartisan basis by five Democratic and five Republican Senators as follows:

Democrats

Virgil Chapman, Kentucky
Paul Douglas, Illinois
Lister Hill, Alabama
Hubert H. Humphreys, Minnesota
Estes Kefauver, Tennessee

Republicans

Guy Cordon, Oregon
Wm. F. Knowland, California
George W. Malone, Nevada
Leverett Saltonstall, Massachusetts
H. Alexander Smith, New Jersey

This bill has been referred to the Senate Labor and Welfare Committee of which Elbert D. Thomas of Utah is chairman. Other members are:

George Aiken, Vermont
Forrest Donnell, Missouri
Paul Douglas, Illinois
Lister Hill, Alabama
Hubert H. Humphreys, Minnesota
Wayne Morse, Oregon
James Murray, Montana
Matthew Neely, West Virginia
Claude Pepper, Florida
H. Alexander Smith, New Jersey
Robert Taft, Ohio

The membership of the Subcommittee on Public Health which will pass on the bill before it goes to the full committee had not been appointed at the time of going to press.

In the House the Local Public Health Services Bill in the form originally considered by the Interstate and Foreign Commerce Committee of the 80th Congress was introduced by the same Congressmen who presented it last year, J. Percy Priest of Tennessee and James I. Dolliver of Iowa. Their bills are numbered respectively, HR 267 and HR 785. The Chairman of the House Committee on Interstate and Foreign Commerce is Robert Crosser of Ohio, with other members not yet announced.

Lemuel Shattuck—Still a Prophet

The Vitality of Vital Statistics *

HUGO MUENCH, M.D., Dr.P.H., F.A.P.H.A.

Professor of Biostatistics, Harvard School of Public Health, Boston, Mass.

SOME hundred years ago, Lemuel Shattuck defined statistics as "the science or art of applying facts to the elucidation and demonstration of truth" (283).† He called it "the basis of social and political economy, and the only sure ground on which the truth or falsehood of theories can be brought to the test."

Shattuck was anticipating (and refuting in advance) objections which would be raised to the fifty recommendations set forth in the *Report of the Sanitary Commission*. Since so much of the *Report* is based on the analysis of vital data in Massachusetts and elsewhere, the expected objection arises very early. The hypothetical Philistine says: "I don't think much of your statistics; you can prove anything by figures." The ring of this is all too familiar to the ears of a statistician, who frequently finds himself in the position of priest of a religion which, alternately reviled by the laity, is again called on by them to pull a prolific rabbit out of a magic silk hat —or, perhaps, in this case it should appropriately be a dunce cap.

Carefully defining what he means by "statistics," Shattuck goes on to point out that they do not consist merely, or even largely, of columns of figures. He uses figures, he says, as the representatives of facts, and as such he finds them "far more useful and important than the fiction and theory, the assumption and assertion that have occupied so much of public attention."

He very clearly realizes the function of figures in statistics when he says that "combination and deduction are required to give them full effect." The entire *Report* is an excellent example of the intelligent use of numerical data for the deduction of justified conclusions, which is the essential groundwork of a science. A science develops, as a rule, through the advent of minds which can organize recorded knowledge, deduce general relationships, and test them against experience. Such minds are never plentiful: at times a constellation of them arises, to be succeeded by a long sterile period. Shattuck's was one of the earliest of such minds to appear in our science of public health which, after all, is not very old even as measured in terms of recorded history.

Logical thinking has presumably been practised since some remote grandfathers freed their front paws from the chore of walking, or of swinging through trees, and began to use them for the purpose of taking their universe apart to see what made it tick. Even so, most of what we like to call "thinking" is far from logical, and the human race is subject to periodic mass retreats from reason. A Greek Golden Age is followed by a period of medieval obscurity, and a Renaissance of liberal humanitarianism by an eclipse of totalitarian dogma. Yet the night is never com-

* Presented before the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

† Numbers in parentheses refer to pages of the original *Report*.

pletely black, any more than the day is without shadows. The tools of intellectual progress are always at hand for him who has the ability and the will to use them, and no age is without its examples of illustrious heretics who dared stake and concentration camp to maintain "Eppur si muove!"

One of the most powerful tools of logical reasoning is mathematics, and quite regularly the organization of new knowledge and the departure from accepted beliefs is along the roads of mathematical synthesis and analysis. It should not be surprising that Shattuck's attack on his problem was couched in statistical terms — or, if you prefer, that a statistical mind of high order produced a logically outstanding statement of problems which could, at that time, be seen only indirectly; and propounded a solution so complete in its general terms that we have not yet caught up with all its implications.

For, mind you, there was no bacteriology at the time of the *Report of the Sanitary Commission.* Shattuck speaks, as did the eminent physicians of his day, of exhalations and effluvia, of bad airs and of stinks. Since air is to blame for much "zymotic" disease, he becomes curious about meteorological changes and analyzes them in some detail (143). He recommends that stations be set up to study changes in the weather (no mean task in the Boston area) and to relate such changes to the occurrence of various diseases. He points out that some gases, such as hydrogen sulfide, when present in any appreciable amount are a direct danger to health. This may be regarded as at least an embryonic approach to industrial hygiene.

With the advent of bacteriology, cause and effect of "zymotic" diseases became direct and simple; perhaps too simple. An increasing number of us are wondering today whether the role of meteorology in the epidemiologic picture has not been too much neglected; whether we might not with profit return to this recommendation of the *Report* and pursue it farther to see whether it could not yield keys to a few of the many doors still locked against us.

Most of the *Report,* being essentially statistical, deals with relationships that can be measured. It may be noted that Shattuck, influenced as he naturally was by current medical speculation, still had the statistician's obstinate reluctance to accept ideas that he could not support with numerical data. He quotes Chadwick, for instance (188), at some length on the dangers of cemeteries to the public health—but he prefaces the quotation with the statement that Massachusetts has not yet experienced these evils; at least to any great extent.

Shattuck's statistical sources were, by today's standards, fragmentary and sometimes of dubious reliability. Yet he seized on them and milked them dry of reliable conclusions, while avoiding many pitfalls into which he might easily have stumbled. Part of his argument is based on average ages at death, but he points out the fallacies underlying comparisons on this basis (106) and is careful to restrict his own conclusions to similar groups. Clergymen, he notes, over a long period of years died at an average age of 63.5; in more recent years, they have been dying, on the average, 7 years earlier (85). Physicians, similarly, have lost 9 years of life compared to earlier periods (86). But he insists, over and over, that the best measure for comparison, when available, is the specific death rate according to age and other factors (139).

The basic argument of the *Report* is simple and straightforward. Mortality conditions were better in Massachusetts in earlier years; some causes are now making them worse; if such causes have been newly introduced, they can be removed, and conditions restored to at least their previous levels.

Various demonstrable factors are associated, in some areas, with mortality rates higher than those of other areas. At least some of these factors can be eliminated and this elimination should bring the higher rates closer to the lower ones.

Again and again, it is pointed out that mortality increases with urbanization. In cities, the increase is associated with crowding and with what we should now call "socio-economic" factors. Infant mortality, in 1830 already twice as great in Boston as in two "country towns," has risen by another half in 15 years more (82). Mortality in other young age groups has kept pace; older people are about holding their own. Why have these mortalities increased? Well, for one thing, "zymotic" diseases have doubled on the scale of proportional mortality. In 1810–1820, they produced 16 per cent of all deaths (90) and, in 1840–1849, 32 per cent (92). Shattuck calls these diseases the "Index of Public Health." Certain of them have increased enormously in Boston, such as smallpox and scarlet fever. The "typhus" fevers, including typhoid, have not increased and, in fact, are relatively more of a problem in the country. Boston has, on the other hand, a much larger share of the dysenteric diseases of childhood (100). Detailed tables are devoted to the analysis of deaths from tuberculosis (94), which not only causes one-seventh to a quarter of all deaths but takes its victims out of the best and most productive part of the life span. It is emphasized that there is no hope of cure, once the disease is established (98)—it must be controlled by prevention.

Why is there this increase in what we should now, in general, call the infectious diseases? For one thing, it is pointed out that known preventive measures have been neglected: the smallpox vaccination laws have been emasculated (180). For another, people are being herded into smaller and smaller circles. To show the effects of this, English data are quoted (43) showing the relationship of crowding to mortality rates in London. Socio-economic factors are brought in: in Liverpool, even the gentry have a death rate equal to London's worst, or 29/1,000; among workers, it is over twice as high (44) to reach the horrifying figure of 67 persons dying per year in each thousand of the population.

From the Census of Boston, Shattuck takes survivorship curves (102) for various population groups. According to these, overall life expectancy in Newton is similar to that in England, or slightly less. Boston's situation is very much worse while Boston Catholics are very definitely in worse case still. Boston Catholics in those days were, of course, very largely the recently arrived and still economically desperate Irish immigrants. Of them, the *Report* has a great deal to say (200): as the population of Boston becomes more largely foreign born, increased crowding is only one of the bad results. The new citizens contribute more than their share of delinquency and disease, while benefiting out of proportion from school taxes and hospital beds.

In the fifty recommendations for the improvement of health conditions in Massachusetts, it is not surprising to find the need for the provision of vital data eloquently stressed and a system of collection expounded in considerable detail. The twelfth recommendation (126) asks that census information be so gathered and made available as to be of real use to the hygienist. Shattuck says: "An exact knowledge . . . of the living inhabitants . . . is the first . . . element, for estimating their sanitary condition." He then enumerates the facts that should be collected: a list not greatly different from one we might make today (128). He points out one essential: this informa-

tion must be known for each individual, and not pooled in groups (130). He also recommends a more modern system of age grouping than that hitherto employed.

Shattuck finds, as do many of us, that ten years is a long time between censuses. The State Constitution at that time provided for state censuses taken during the same years as the federal ones (133). He points out the absurdity of this and recommends that state censuses be spaced evenly between federal ones: a recommendation since then followed. The blame for the only moderate success of this measure can hardly be laid at Shattuck's door.

In the fourteenth recommendation (135), the need for a comprehensive system of recording vital data is set forth at length. It is pointed out (139) that age-specific death rates are the only fair bases of comparison and that these cannot be found without knowledge of the ages of the population and the ages at which they die. A table is presented (140) illustrating the effect of different population compositions on the crude death rate, and a warning is sounded against the not entirely extinct habit of comparing the salubrity of occupations on the basis of the gross mortalities of the groups involved, without taking into account what differences there may be in the ages of those who work at different tasks. In order to study the natural history of populations, says the *Report,* complete data on births are as necessary as those on deaths, and they should be collected and registered just as carefully.

Shattuck ends this recommendation by a brief statement of twelve principles (141), here even further abridged:

1. Mortality varies uniformly with age.
2. Maintenance of the population is based primarily on the number of married couples in the fertile ages.
3. Excessive births are a *cause,* not a *consequence,* of high mortality rates.
4. Mean age at death and crude death rate are fallacious measures of health conditions.
5. Comparing the dangers of different occupations on the basis of mean age at death or of total mortality of the workers is fallacious.
6. Previous rates cannot be compared with present ones on these bases.
7. Age-specific death rates form the only legitimate basis for comparisons.
8. Immigration and emigration usually distort the age distribution of a population, and so its crude mortality rate.
9. Morbidity and mortality should be studied separately by age, sex, season, occupation and other factors.
10. An accurate census and accurate vital statistics are basic to knowledge of a population, and a sanitary survey is useless without them.
11. The English system of age grouping should be adopted instead of the present, irregular one.
12. Statistics should be under the supervision of the Board of Health to secure uniformity over the entire State.

We could hardly ask for a more comprehensive statement of why statistics are useful, and what they must include in order not to be misleading. The sixteenth recommendation (149) adds a suggested list of causes of death to supersede the medical classification currently in use, which is considered unsatisfactory. Shattuck feels that the causes of disease deserve more attention than does the disease itself (150), and endeavors to construct a classification according to etiological principles. Although his system of causative agents is based on notions a century old, his principle has a very modern sound: particularly in view of our continued inability to get away from a classification based partly on etiology and partly on regional pathology.

Throughout the *Report,* one is struck by the rarity of occasions on which Shattuck is led very far astray by concepts of disease current in his time, some of which look ludicrous enough from the proud point of view of our present rung on the ladder of epidemiologic knowledge. He is a hard-headed business man, and he insists on facts.

As a business man, also, he abhors

waste in the human population as he would in his publishing house. Unnecessary deaths are a criminal waste. They not only cause misery to the individual concerned and to his family, but they throw helpless widows and orphans on the community and so deplete its resources. Unnecessary illness is much the same. It causes suffering; it also reduces productivity and leads to additional expenses. Lacking adequate morbidity statistics for Massachusetts, Shattuck quotes liberally from English sources (174) as to days lost per year due to sickness. He proposes, in the twenty-fifth recommendation (171), that morbidity surveys be carried on to determine the exact load of disease in Massachusetts. In the meanwhile, he is quite sure that conditions here are worse than in England. His reason is simple and convincing: various sickness insurance companies have been formed in Boston and have used English experience as a basis for their premium rates. They have uniformly gone into bankruptcy (177)! He estimated that, in 1849, at any time, over 5 per cent of Boston's population was sick.

In order to do justice to Shattuck's grasp of statistical method—to show how firmly his conclusions are based on sound quantitative reasoning—almost the entire book would have to be quoted. Did he think logically because he was a trained statistician? Or did he become interested in statistics because he had a logical and orderly mind? The choice of answer does not seem to matter greatly.

What does matter a great deal is that by use of Laplace's "good sense reduced to arithmetic" a man, although not a physician, was able to see the essentials of a complicated question and to postulate a workable answer. Perhaps we should say "*because* he was not a physician," since he was to some extent able to stand outside the body of accepted medical ideas of his time and to view them with a certain disinterest and detachment. The lenses he used to help him see more clearly were statistical in their structure.

Medicine and public health, by their very nature, tend to accept and to carry on ideas based on evidence that is anything but solid. The problems are so great; the needs so immediate; the possibility of experiment so difficult; that we easily succumb to the comfortable feeling that whatever we are doing must be of some benefit to a suffering humanity, and should not be questioned. Once a concept is deeply imbedded in our thinking it requires unusual ability and pertinacity to dig through the surrounding layers of custom and association, to bring the concept to the light of day and to subject it to a new and thorough scrutiny.

True enough, vital statistics alone does not enable the questioner to see clearly, to judge soundly, and to act sensibly. But it is an essential tool for the type of mind which Shattuck had; it will be just as essential to the next who may come to tear down old walls and to build new and better on the solid foundations. That is the vitality of Vital Statistics!

Order blank for Report of the Sanitary Commission of Massachusetts 1850 by Lemuel Shattuck appears on page XXXVI.

Lemuel Shattuck—Still a Prophet

The Message of Lemuel Shattuck for 1948 *

C.-E. A. WINSLOW, Dr.P.H., F.A.P.H.A.

Editor, American Journal of Public Health

THE meeting we are holding this afternoon is a striking example of the miracle of the written word. The life of the physical body is brief; but the thoughts of men have acquired immortality through the magic of the pen and of the printing press. We celebrate today the centennary of a printed book through which the ideas of a great pioneer still live and move and have their being.

There are many great books in our field of human thought. Johann Peter Frank, Edwin Chadwick, John Simon, W. T. Sedgwick, Charles V. Chapin produced works which were of compelling influence in their day and are still worthy of our attentive study. But, in my judgment, the *Report of the Sanitary Commission of Massachusetts* is the most outstanding single "Book of Pfophecy" in the history of public health.

My own copy of this work was sent by Lemuel Shattuck to the Mayor of Providence, under date of March 4, 1851, with the following letter from the author which is pasted inside the front cover.

"I take the liberty to forward for your acceptance a copy of the Report of the Sanitary Commission which I have prepared and just published. You will please place it in the hands of the Board of Health or other department of your municipal authorities where it will be most useful. Although it contains many things that are evidently of local application, yet other matters will be found of a general bearing which may be useful in any place. If it shall be means of calling public attention to the causes of disease, and of leading to the adoption of wise measures for their removal it will do much good; and this is my only motive in its production."

Many years later, when there was house-cleaning in the Providence City Hall, this volume was thrown out on the town dump. A discerning citizen observed it there, rescued it, and took it to Charles V. Chapin, the distinguished health officer of the city; and in 1930, Dr. Chapin sent it to me with his "affectionate regards." So it is a precious volume, bearing the signatures of two of the most outstanding leaders of American public health.

Most of the 2,000 copies of this report authorized by the Massachusetts Legislature of 1850 have not been so fortunately preserved; and the original printing is a collector's prize. Perhaps some of you may still find a copy on some obscure and dusty book-shelf. Meanwhile, it must be a great personal gratification to all of us that the Massachusetts Public Health Association and the American Public Health Association have coöperated to produce a complete facsimile reproduction of the original report (omitting only its appendices). This should be the first volume with which the young recruit in public health begins the formation of his personal library.

It is a little difficult for us to grasp the significance of the *Report of the Sanitary Commission of Massachusetts*

* Presented before the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

without an effort to realize the America of a century ago to which it was addressed. In July, 1850, Zachary Taylor died and Millard Fillmore took the oath of office as head of a nation of 23 million people. For transportation, the bicycle was available, and Shattuck notes with admiration the wonders of the Morse telegraph system. Only in the 50's, was the New York Central Railroad completed from New York to Albany, and the laying of the Atlantic cable begun. Airplanes, automobiles, electric trolleys, incandescent lamps, turbines, submarines, telephones were all in the womb of the future. The very land on which many of the hotels we occupy now stand was a waste of water and mud, the "Back Bay," not yet filled in for human occupancy.

There had been "boards of health" in Baltimore, New York, Philadelphia, and other large seaboard cities established under the threat of yellow fever in the 1790's; and a law passed in 1849, during a cholera epidemic, authorized towns in Massachusetts to establish boards of health; but these "Boards of Health" were still skeleton organizations dealing only with acute epidemic emergencies and particularly obnoxious local nuisances. The Board of Health of the City of Boston was established only in 1872, after the great fire of that year. There were, of course, no state boards of health, Massachusetts leading the way in 1869. As Dr. Henry P. Bowditch said, Shattuck's report "fell stillborn from the hands of the State printer." G. C. Whipple tells us that "eight years later, Governor Banks, who had been a member of the Sanitary Commission, did not even remember that he had signed the report."

So, in a world in which only Edwin Chadwick in England had any dim conception of an organized, continuing program of positive health promotion, Lemuel Shattuck formulated his vision of the future. I like to think of this ex-school-teacher, publisher, book seller, member of the State Legislature, and good citizen—with his strong and eager face (rising over a high collar and black bow-tie in his portrait), sitting at his desk and beginning to write (probably with a quill pen and on foolscap paper) as follows:

"The Commissioners, appointed on the third day of July last, 'to prepare and report to the next General Court, a plan for a Sanitary Survey of the State, embracing a statement of such facts and suggestions as they may think proper to illustrate the subject,' have considered the matters referred to them, as far as the limited time at their command, and other circumstances, since their appointment would permit, and submit their *Report*."

Little did he think that a century later, an American Public Health Association, of eleven thousand members, would hold a special meeting to attest the lasting significance of what he wrote, a bold pioneer gazing out from a mountain top through the mists to a future promised land.

He states the problem in terms which are as valid in 1948 as in 1849.

"We believe that the conditions of perfect health, either public or personal, are seldom or never attained, though attainable;—that the average length of human life may be very much extended, and its physical power greatly augmented; that in every year, within this Commonwealth, thousands of lives are lost which might have been saved; that tens of thousands of cases of sickness occur, which might have been prevented;—that a vast amount of unnecessarily impaired health, and physical debility exists among those not actually confined by sickness;—that these preventable evils require an enormous expenditure and loss of money, and impose upon the people unnumbered and immeasurable calamities pecuniary, social, physical, mental, and moral, which might be avoided;—that means exist, within reach, for their mitigation or removal;—and that measures for prevention will effect infinitely more than remedies for the cure of disease."

He perceived that "the condition of perfect *public health* requires such laws and regulations as will secure to man associated in society, the same sanitary

enjoyments that he would have as an isolated individual; and as will protect him from injury from any influences connected with his locality, his dwelling-house, his occupation, or those of his associates or neighbors, or from any other social causes." Still more remarkable is the fact that Shattuck realized the importance of the educational, as well as the legal approach. "But whom does this great matter of public health concern?" he asks. "By whom is this subject to be surveyed, analyzed, and practically applied? And who are to be benefited by this application? Some will answer, the physician, certainly. True, but only in a degree; not mainly. It will assist him to learn the causes of disease; but it will be infinitely more valuable to the whole people, to teach them how to prevent disease, and to live without being sick."

The *Report* begins with an admirable historical summary, the preparation of which must have taken weeks and weeks of Shattuck's time and more than exhausted the $50 allotted to the Commission for the purchase of books on the subject. It traces the progress of the "Sanitary Movement" abroad — in France, Germany, and England, and of the beginnings of the movement in this country. It includes an invaluable review of the outstanding epidemics which had occurred in Massachusetts, from a mysterious pestilence which had almost exterminated certain local Indian tribes in 1618; and closes with statistical analyses of mortality by place, season, occupation, and cause which are still of background significance to the student of vital statistics.

The major section of the *Report* is devoted to specific practical recommendations, fifty in number; and it is here that Shattuck's combination of long-range vision and practical common sense is most astonishingly manifest. Of the fifty recommendations—all at the time new and untried principles or policies—careful analysis shows that no less than thirty-six are now universally accepted practice—not only in Massachusetts but throughout the Union. They provide, first, for a sound basis of public health administration, including an overall state health law; a State Board of Health (whose membership should include two physicians, a counsellor at law, a chemist or natural philosopher, a civil engineer, and two other persons) with a paid secretary; a local board of health in each town with a secretary, required to make an annual written report; and for special sanitary surveys of particular cities, towns, and localities (a foreshadowing of the work of our Committee on Administrative Practice). Recommendations are specific and detailed with regard to vital statistics, including a decennial state census, uniform nomenclature for causes of death and of disease and collection of data with regard to locality, age, race, sex, occupation, housing, and economic status. In the field of environmental sanitation, Shattuck emphasizes the control of nuisances endangering human life or health (including specifically the smoke nuisance); the supervision of the construction of new dwellings, factories, or other buildings, and the mitigation of sanitary evils arising from overcrowded lodging-houses and cellar-dwellings; the sanitation of school houses; and exact observation of "the effect of mill-ponds and other collections or streams of water, and of their rise and fall, upon the health of the neighboring inhabitants"; a sound basis for the study of the epidemiology of malaria. Specific recommendations provide for control of the sale and use of unwholesome, spurious or adulterated articles designed for food, drink, or medicine, with special reference to patent medicines and other nostrums and secret remedies.

In the area of communicable disease

control, every town should be required to provide periodical vaccination against smallpox; and three recommendations deal with maritime quarantine and the protection of the health of passengers and merchant seamen, a program which was soon to be developed by the U. S. Marine Hospital Service. Shattuck's emphasis on tuberculosis is of special interest. He says:

> "The occasional visit of the cholera, or some other epidemic disease, creates alarm, and precautionary measures are adopted for prevention. But where is the alarm and precaution against a more inexorable disease, which, in this state, in every day in every year deprives more than seven human beings of their lives? Over this disease curative skill has little or no power. It generally goes on from its commencement to its termination, uncontrolled and uncontrollable by any remedies as yet discovered. Cholera, typhus, scarlatina, though terrible in themselves, when compared with this disease, are far less so in fatality. *But it may be avoided,* before it attacks. Its onset and its development may be prevented. And if it is ever to be ameliorated or eradicated, it can only be done by prevention, and not by cure."

The precise answers were not then at hand; but Shattuck faced the problem and urged "that the causes of consumption, and the circumstances under which it occur, be made the subject of particular observation and investigation." In other recommendations, the *Report* lays the foundation for programs of child health by the training of "parents, and others to whom the care of those in infancy and childhood are intrusted," to "understand and discharge their duties so that a good foundation may be laid for vigorous manhood and old age"; and by measures taken "to ascertain the amount of sickness suffered among the scholars who attend the public schools, and other seminaries of learning." Finally, two of the most far-sighted recommendations in the *Report* suggest: "that institutions be formed to educate and qualify females to be nurses of the sick"; and "that persons be specially educated in sanitary science, as preventive advisers as well as curative advisers." In considering the first of these suggestions, we must recall that in 1848 Florence Nightingale had not yet established her pioneer training school in England; and that this astounding Boston book seller based his recommendations on his knowledge of Pastor Fliedner's school at Kaiserswerth, from which the Lady of the Lamp drew her own inspiration. With respect to education in preventive medicine, Shattuck foresaw the need for something like our ten accredited Schools of Public Health, and for the attempt—not even yet too successful—to introduce the concept of prevention into medical education.

Against these 36 recommendations whose soundness has been demonstrated by their full incorporation into the routine practices of public health, I find only 4 which experience has shown to be unimportant or, in some degree, unsound. One of these relates to a minor detail with regard to the format of printed annual reports. Another calls for control of inquests by the Board of Health; and still another for the management of cemeteries by the Board of Health. The fourth and last dubious recommendation of the *Report* urges that "whenever practicable, the refuse and sewage of cities and towns be collected, and applied to the purposes of agriculture." This was wholly in accord with the best thought of the time in England; but experience has shown that such a method of disposal is not generally "practicable" on economic grounds.

There remain ten recommendations of the *Report* which are of particular interest to us. They are as sound as the 36 proposals which have been generally accepted; but their importance has not yet been fully realized. They constitute direct and immediate challenges to the public health profession of 1948.

Three of these recommendations (XVII, XXI and XXXVIII) relate to the vital problems of housing and planning. We have accepted the necessity for health department control of the most obvious and glaring defects in housing; but this is merely curative and not preventive sanitation. Shattuck saw farther into the future. He demanded that "in laying out new towns and villages, and in extending those already laid out, ample provision be made for a supply, in purity and abundance, of light, air and water"; "that open spaces be reserved in cities and villages for public walks; that wide streets be laid out; and that both be ornamented with trees." He urged that "tenements for the better accommodation of the poor, be erected in cities and villages." It is true that he looked chiefly to private philanthropy to attain the latter end; but we know today that only public assistance, on the federal level, can possibly meet our national needs. We have city planning boards in our cities; but—with shining exceptions, such as Philadelphia and Los Angeles—they are not receiving full and continuous public support. We began, with brilliant success, under the National Housing Act of 1937, a real program of slum clearance and housing for the lower income groups; but the House of Representatives, through reactionary committees, killed public housing bills in both the 79th and the 80th Congress. Except for temporary war housing, not a single dwelling for low income families has been built for nearly a decade; and with increasing families and inflation, slum conditions become more deplorable every year.

A second challenge of the 1850 *Report* is found in its suggestion (XXX) that local boards of health should make "careful observation of the sanitary evils of intemperance, and the local and personal circumstances under which they occur." We have only begun to realize that alcoholism is not primarily a moral or a social problem but a medical problem; and, in Connecticut, and a few other areas, it is being attacked along that line.

Another of Shattuck's recommendations (XXXII) faces the challenge of mental and emotional disease, probably the greatest single objective of the public health program of the future. His concrete suggestion is a limited and perhaps, in its actual form, an unsound one—that "the authority now vested in justices of the peace, relating to insane and idiotic persons, not arrested or indicted for crime, be transferred to the local Boards of Health." Yet his fundamental assumption that the person of unsound mind presents a health problem rather than a legal problem is wholly valid. All of our dealings with such persons must be guided by psychiatric expert knowledge and not, as is still too often true, by archaic and barbarous commitment laws. In further reform of these laws and in providing preventive services which will avoid the necessity for resorting to legal procedures at all, the health officer faces a major opportunity.

Two of Shattuck's recommendations embody minor—but significant—suggestions as to the extension of our knowledge of disease prevalence by more careful and detailed records to be kept by private physicians (XLVI) and by systematic records to be kept in each family "of the physical and sanitary condition of its members" (XLVIII).

Finally, three recommendations open up wide vistas in the area of public health education. They suggest that "a sanitary association be formed in every city and town in the state, for the purpose of collecting and diffusing information relating to public and personal health" (XXXVII); that "clergymen of all religious denominations make public health the subject of one or more discourses annually, before their congre-

gations" (XLVII); and that "individuals make frequent sanitary examinations of themselves, and endeavor to promote personal health, and prevent personal disease" (L). The establishment of "sanitary associations" in every city and town is precisely the object of the National Health Council, whose recent reorganization we hail with such keen satisfaction. The clergy could certainly be enlisted more generally in our cause. The "sanitary examination" which Shattuck proposed was not "an annual health examination."; but the much more important continuing study of problems of personal hygiene which is the chief objective of health education.

In general, it will be seen that the 1850 *Report* laid a sound basis for the development of health administration, vital statistics, sanitation, and control of foods and drugs. It opened the way for maternal and child health, school health, and the study of tuberculosis. It—curiously enough—ignored domestic (as opposed to maritime) isolation and quarantine, so far as major recommendations were concerned. It could, naturally, have no vision of the future developments of bacteriology, or immunology (smallpox vaccination being the only specific procedure available). The causative agents of venereal diseases were unknown and effective drugs for their treatment not available. Public health nursing was not to come for a quarter of a century; and medical care was not recognized as a serious problem, although figures are quoted to indicate that the annual charges of physicians of the state averaged $800, with average collections of $600. On the whole, however, it is quite astounding that a report, written when public health practice was in its infancy and public health science yet unborn should, out of 50 recommendations, include 36 which have been universally accepted and 10 more which are now in process of attainment. The general framework of the public health program of 1948 was embodied in the *Report* of 1850.

Time does not permit analysis of the later sections of the *Report* which deal with "Reasons for Approving the Plan Recommended," "Objections Answered," and a "Closing Appeal," to physicians, clergymen, educated men, the wealthy and philanthropic, the people as a whole, the periodical press, the cities and towns and the state, to support the proposed program. Shattuck uses the now familiar—but still highly fruitful—device of comparing the cost of sickness with the cost of health. He estimates the burden of preventable disease in Massachusetts at $7,512,000 a year; and he asks for the very modest sum of $3,000 a year to support his proposed State Board of Health! Many of the anticipated objections to his plan have a familiar ring, today: "It may be said,—'The measure is not applicable to this State; it may be well enough in some other places and countries, but we do not suffer evils which require such remedies for their removal; no people are more healthy than we; we are well enough as we are.'" This is precisely the argument advanced to avoid the issue of health insurance for the groups of modest income in 1948. "It may be said,—'This measure will interfere with private rights. If I own an estate haven't I the right to do with it as I please? to build upon it any kind of house, or to occupy it in any way, without the public interference?'" Here is the basis of the current opposition to sound housing legislation. "It may be said,—'We acknowledge that all you say is reasonable and cannot well be gainsayed; but we are a business-like, a money-making, and money-loving people. We are too much occupied to consider these matters. So many other things take up our attention that we haven't time to examine, much less to carry out your measure; and people are

not up to it as yet.'" Is this not precisely and exactly the attitude of the 80th Congress toward the vital problem of slum clearance and homes for the families of low income in 1948?

This is truly an astounding document. Its final appeal closes with a glowing tribute to the great Commonwealth under whose auspices the *Report* was produced. Shattuck points out the primacy of the leadership of Massachusetts in free public education, in registration of births and deaths, in provision of public facilities for the blind, and the deaf and dumb, in demonstration of the value of smallpox vaccination and of anesthesia. "God save the Commonwealth of Massachusetts" —he quotes—"'There she stands'; a bright morning star in the system of the Union." The publication of the *Report* in 1850 was one of the most effulgent rays ever emitted by that star.

The true significance of this *Report* is not its specific content, although much even of that is still pertinent to the present day. Its vital message for 1948 is the spirit of its approach—for the spirit of man is not something ephemeral. It is the determination of Shattuck to further the cause of all of the people, his fiery enthusiasm for that cause, his vision of new challenges and his unwavering faith in ultimate victory —these are the essentials—the living forces of the document. As you read it, you will gain new conviction of the true values of the cause which this convention of the American Public Health Association represents. Our calling is not merely to a useful and respectable profession—but to a crusade. You may remember the old tale of the three workmen, who were asked what they were doing. "I am earning my living," said the first. "I am dressing stone," said the second. "I am building a cathedral" said the third. Shattuck reminds us that we are building a cathedral.

Nor is our task a static routine but an ever-advancing and ever-widening adventure in the cause of man. We can, with great advantage, use standard methods for routine procedures; but our program as a whole must never become standardized. We must open our vision and call upon the resources of our courage to attack those problems which Shattuck foresaw, such as housing, mental hygiene, alcoholism, and health education; and those he did not vision, such as geriatrics and rehabilitation and medical care. We must not be disheartened if progress is slow. The modest state health organization which Shattuck urged for Massachusetts was not attained till nineteen years after the *Report* appeared and ten years after his own death; but it was, at last, established along exactly the lines which he laid down.

We have, today, far stronger arguments than Shattuck had to back our appeals. During the thirty years between 1915 and 1945, the United States took part in the two greatest wars of history. In those wars, between half a million and a million lives of our citizens were lost in battle. During the same thirty years, the reduction in our civilian death rate saved over six million lives.* Even World Wars are trifling and unimportant incidents, by comparison with the triumphs of public health—perhaps the most remarkable social phenomenon in the history of mankind.

This is the great cause which Shattuck served in 1850. It is the cause which you and I serve today. If we pursue our vocation with Shattuck's zeal and courage and vision and faith, the second hundred years of public health may be even harder than the first; but they will certainly be even more glorious.

---

The Montefiore Hospital Home Care Program*

MARTIN CHERKASKY, M.D.

Home Care Executive, Montefiore Hospital, New York, N. Y.

ENUMERATING services which the Montefiore Hospital Home Care Program provides for its patients, and the gratifying results which we have achieved, would be telling only part of the story. The basis of the program, which carries a step further the philosophy which Dr. Bluestone, our Director at Montefiore Hospital, has been expounding for some three decades, may be of even greater significance. When I was in medical school, not so long ago, we were taught that it was important to think of a patient as a whole, and not just to examine a limb or an eye. We have now come to a point in the practice of medicine where we must broaden that point of view. When we think about a patient, we should think about him not only as an organic and spiritual whole, but also as a whole in society. It is no more fair or useful to separate a man from his environment than it is to divide him into separate and independent parts.

Our hospitals, despite their stress on scientific medicine which includes diagnostic machines, laboratory examinations, therapeutic procedures, and all of the other wonderful accomplishments which have raised the level of medical care, have held back from an understanding of sick human beings as social human beings. When a patient presents himself to a hospital with certain symptoms these days, he comes in as a stranger, his immediate illness is diagnosed, and he is relieved of his condition. Unfortunately, however, he too often returns to the same situation which may have given rise to his illness. To understand what caused this patient to become sick, it is necessary to know what sort of family he has, where he lives, what kind of clothes he wears, what food he eats, what kind of employment he has, and how he reacts to these factors. These and similar facts of life make up man as a social being, and may be more provocative in the origin of his disease than the germ which has been isolated from his sputum in the bacteriology laboratory. The hospital must seek a knowledge of these factors as eagerly as it seeks knowledge in the field of scientific medicine.

This introduction is, I believe, vital to an understanding of "Home Care." Our hospital, in extending its services into the home on an extramural basis, has begun to learn many things about the patient which can only be learned when he is in the bosom of his family. To the doctors on the program it has brought a new realization of the importance of social factors in disease. This is true of any disease. It is particularly true of long-term disease where the stress of illness brings about many changes in the relationship of the patient to his family, both emotionally and economically. Montefiore Hospital in New York has not only made its scientific machinery available to pa-

* Presented before a Joint Session of the Public Health Nursing and Medical Care Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

tients who live miles from its walls, it has also begun to learn new reasons why a patient becomes sick and why his illness is prolonged. This may indeed prove to be the most important contribution of the Home Care Program.

For the years 1947–1948, our Home Care Program has received $80,000 from the New York Cancer Committee, and $14,000 from the Greater New York Fund on an extra budgetary basis.

To illustrate the thinking which goes into the selection of a home care patient and what is done for him, it might be well to have you follow a typical case.

John J. was admitted to the hospital with some undetermined abdominal disease, and after thorough investigation by the clinicians and by the laboratories of the hospital, it was found that he had a cancer of the colon. He was subjected to major surgery, at which time it was found that the disease had progressed so far that the entire cancer could not be removed and he was left with a colostomy. Here is a patient who will ultimately die of his disease, but he may have six months, a year, two years or more to live. He requires nursing care, colostomy irrigations, watchful attention for complications, medication, and someone to help him with his food. He may be semi-ambulatory or bedridden. In any case, he is a sick man. But he may no longer require the special facilities of the hospital. Indeed, even if there were plenty of room for him in the hospital, he might do much better in some other environment.

The Department of Home Care was notified about this patient, and our doctor saw him for the purpose of determining whether we could provide him with a level of medical care at home which would be in conformity with our best hospital standards. In addition to being medically eligible, the patient was investigated and determined to be socially eligible. Every patient who is admitted to Montefiore Hospital has a social service "work up." When he is evaluated for Home Care, the social service worker reviews the patient's record, interviews him, interviews members of his family, and investigates the home. Since no patient is returned to his home unless this is in his best interests, it is obviously important that the family situation, the physical facilities of the home, and the patient's relationship with other members of his family should be such as to encourage the return to his home.

Many of us think of families and just naturally assume (at least when we are younger) that all parents love their children and that all children love their parents. Most of us live long enough to find out that this is not necessarily so. When return of a patient to his home is contemplated, it is important to know what bonds exist between him and his family—Are they still strong, after the disrupting effects of a long illness? These questions must be answered before it can be decided that it is best for a patient to return to his home. Some families seem not to want the patient back, but closer investigation reveals that the reason is not lack of love, but fear—fear of illness, fear of impending disaster, fear of inability to do what is required. If the fundamental attitudes are sound, all of these fears can be overcome by careful handling and good service. Some of the families who were doubtful proved to be among the best in our experience.

When it has been decided that a patient is medically and socially eligible, the patient goes on Home Care and receives the following services:

1. Medical service, around the clock, seven days a week. Specialists are available for the patient in his home, such as orthopedists, ophthalmologists, and surgeons. Many medical procedures such as abdominal taps and blood transfusions can readily be done in the home.

2. Social Service—The social worker who cared for the patient on the ward follows him into the home to help him and his family with any problems that may arise, and interprets the program to the family.

3. Nursing—The Visiting Nurse Service of New York, by contracts with us, visits each patient at least once, even in those cases where we do not foresee any need for Visiting Nurse Service, since their experience in the home will give us a good evaluation of the patient and of the patient's need for nursing. In addition, the nurses have two other important functions. They provide nursing and they teach. The teaching is, in some respects, the most important part of their job. They often teach a member of the family to become an expert nurse in the care of a particular patient.

4. Housekeeping service—We provide housekeeping service 5 to 10 hours per week. We find that this is very helpful since many of the patients who would otherwise have to remain in the hospital can well be taken care of at home if there is someone to help with the heavy housework. We have discovered that a woman is more than just a housekeeper in the home—that the mother, when she returns to the home, even though she no longer is able to do the dishes and wash the floors, can still be the rallying point for the entire family.

5. Transportation—Transportation to and from the hospital is provided, and there is a free interchange of patients between the hospital and the home. Dr. Bluestone pointed out [1] that Home Care is, in essence, an extension of the hospital into the home. There are none of the facilities of the hospital to which we cannot bring our patients by ambulance. The inconvenience to the patient is little greater than moving him from the 4th floor of the hospital to one of its laboratories.

6. Medication—We supply the patient with all medications, with hospital beds, wheelchairs, special mattresses, braces—anything that contributes to the welfare of the patient and which can be transported.

7. Occupational Therapy—We have a full-time occupational therapist who visits the patient in his home. This serves several purposes. First, it is a morale builder and certain corrective procedures can be taught to the patient. Second, for some patients it may in a small way alleviate the ever present financial difficulties.

8. Physical therapy — Our physical therapist also enters the home to treat the patient.

What are the results of our program? Let us consider the financial benefits first even though they may not be the most important. In the first twenty months of our program, we have provided something over 23,000 days of patient care. The average cost per patient day was less than $3 per day which compares quite favorably with the present cost of hospital care of $12 to $15 per day. It is, however, not of importance to have a product which is only cheaper. It must be as good or better. Home Care for patients who are suitable is not only "as good as" hospital care—it is infinitely better. If there were many empty hospital beds, a patient who is suitable for Home Care would still do much better in his home than he could possibly do in a hospital. In a hospital, a patient is one of many. He has to give up many of his own little private privileges and desires for the benefit of the group as a whole. In Home Care, we have provided the best of scientific medicine and the best in environment. He is an individual in his own bed with his own type of bedclothes, and he can have the window up or down as he sees fit. He can have his breakfast when he wants it and not when the dictates of hospital discipline compel. A patient on the ward in a hospital may be looked

at every day by a doctor, but he is not always "seen." When a doctor visits a patient in his home two, three, or four times a week, he is the sole recipient of the doctor's attention and care. A doctor on the ward may find greater interest in some patient three beds down the ward who is clinically more exciting or more interesting. Where the special facilities of the hospital are no longer needed, the rigidity and chilliness of a hospital can be profitably exchanged for the flexibility and warmth of the home.

Let me cite a case which illustrates the individualization of medical care and the well organized team which can be brought to bear on the patient in the home:

Jean J. had a growth involving her spine. An operation was performed and a large bony segment was removed. This happened about six years ago. During the intervening time Jean spent more than one year in a body cast and, because of the defect in her spine, was told she could never walk. She was seen in some of the best hospitals, but here was a patient permanently consigned to bed, a hard fate for a 29 year old girl to endure.

Eight months ago Jean came on the Home Care Program. She lived in a third story apartment with her widowed mother. The doctor seeing this young woman in her home, developed a much clearer insight into her hopes and desires than could a doctor on the ward where she was just one of a dozen patients bedridden for life. An orthopedist was called in, and after reviewing all the x-ray films, a special back brace was made for the patient. One day the visiting nurse met the doctor at Jean's home and helped her out of bed with under-the-arm crutches, and so began a long period with the doctor visiting three times a week, the visiting nurse three or four times a week, the physical therapist four times a week, massage, encouragement, new Swiss crutches, leg brace, and one day Jean got out of bed and walked to the bathroom for the first time in over five years. By using telephone books as an improvised stair, she was taught to walk up and down stairs. More than six months after coming on Home Care, Jean walked down two flights of stairs, got into a cab, came to our hospital and was presented to our clinical conference. Many of the doctors were surprised to see this "bedridden" patient come in under her own steam. Jean now is progressing toward walking without any supports.

We have salvaged a human being, and this by individualizing her care and by coördinating all the facilities of the hospital and community in their joint fight for health and against disease.

Home Nursing Service in the Health Insurance Plan of Greater New York*

MARIAN G. RANDALL, R.N., F.A.P.H.A.

Executive Director, Visiting Nurse Service of New York, New York, N. Y.

VISITING nurse service at home is included in the list of benefits provided by the Health Insurance Plan of Greater New York. A review of the first year's experience tells a limited, but significant story.

As is now widely known, HIP (Health Insurance Plan of Greater New York) is a non-profit corporation, licensed by the State of New York, operating under New York State Insurance Department regulations. It provides specified benefits for employed persons in New York City who earn less than $5,000 annually, and to their dependents. Pamphlets describing the plan,† state "no limitations on age or amount of service." The medical care includes general medical service at the home, at the doctor's office, at the hospital; specialist, surgical, maternity, and laboratory services; health examinations and preventive services.

The cost, which is shared by the employee and employer, the latter paying at least half of the premium, is $0.56 a week for a single individual, $1.12 a week for a person with one dependent, and $1.68 a week for a person with two or more dependents. Hospital insurance is not included in these costs, but each subscriber must be enrolled in a hospitalization plan as a prerequisite for HIP enrollment.

Group practice and a capitation plan is offered to qualified physicians. A group includes general physicians and specialists, aided by technical personnel working together as a team from an administrative center. Each medical group must meet professional standards set by the 15 practising physicians constituting the HIP Medical Control Board. A capitation of $19.20 per person per year is paid by HIP to each medical group. Considerable thought and study preceded this decision. Apprehension on the part of some persons about the physicians being willing to pay for nursing service and concern by others that if they did not pay for it, the nurses might be asked to make too frequent calls to assist physicians, influenced HIP to put aside 40 cents (80 per cent) per person to cover the cost of the estimated visiting nurse service and to ask each medical group to bear visiting nurse service costs up to 10 cents (20 per cent) per insured person per year. Experience, in the first year, shows that the limited amount of nursing service used was used wisely. No physician asked the nurse to carry out services which he might be expected to give. However, some of the medical groups (not all) voiced disapproval in having any part of their capitation

* Presented at a Joint Session of the Public Health Nursing and the Medical Care Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

money used for nursing service, and wished unused funds to revert to the medical group.

Each medical group is an independent administrative unit which may employ non-medical personnel without HIP approval, and visiting nurse service is one of the benefits which the group agrees to provide. The Health Insurance Plan Nursing Advisory Committee, composed of representatives from both official and private agencies including hospitals, public health, and schools of nursing, recommended that medical groups should not try to set up their own visiting nurse services, and when HIP went into operation in March, 1947, it signed contracts with the three visiting nurse organizations covering the five boroughs of New York City.

Before citing details of these contracts, it is appropriate to mention that, in HIP policies, emphasis is given to the insured persons' free choice of physicians from the medical group and importance is attached to preserving the desirable close doctor-patient relationship essential to effective medical care. For the visiting nurse organizations, the HIP contract did not in any way change their ideas and principles of working with private physicians as they have always worked with the doctors in the community. Nor does a contract with any group change the ideals and principles of the visiting nurse organizations concerning nurse-patient relationship.

THE CONTRACT

It is desirable to have the formal written contract as simple as possible, and provide for changes as needed in a separate statement of procedures. In the HIP contract it is agreed that "the nursing agency will provide visiting nurse service to HIP insured persons subject to the 'Policies and Regulations for Visiting Nurse Service Furnished to HIP Insured Persons' or any subsequent revision of these policies." Thus, the policies and regulations became part of the contract without encumbering it. In addition, the contract states that:

1. The insured person must be under the care of a physician affiliated with a HIP medical group.
2. Nursing visits will be made in the home, within the geographical area served by the nursing agency, and in accordance with nursing agency policies.
3. All nursing visits must be reported to and bills submitted to HIP at the end of each month for nursing services rendered in that month.
4. HIP will pay the nursing agency on a cost per visit basis, according to an annual cost-accounting method recommended by N.O.P H.N. and used extensively throughout this country.

Complete information was not available on which to base an accurate estimate of the volume of nursing service which might be needed or requested, although experiences of insurance companies and visiting nurse organizations were carefully reviewed. The estimate made was knowingly and deliberately set about 50 per cent higher than any other estimates in order to insure adequate funds to provide for an unusual amount of service. This estimate was set at a *ceiling* of 300 nursing visits per 1,000 insured persons per year.

The *Policies and Regulations* for nursing service allowed for flexibility, and included most of the generally accepted policies in visiting nurse organizations such as a list of services provided (sent to all physicians participating in medical groups), hours for receiving calls, methods of obtaining a physician's orders and keeping him informed of the patient's progress, and methods of certifying the eligibility of a patient to receive service as a HIP insured person. Great effort was made to keep the record system as simple as possible; but as visiting nurse organizations know from long experience, the need to report services rendered to many different groups such as welfare departments, insurance companies, industries,

private physicians, and many other groups presents a definite problem. A new contract, such as the one with HIP, will inevitably present an additional need for close supervision of records and the learning of another set of regulations regarding many record items. This is a fact, not a complaint.

One policy of particular interest was that the nursing agency could accept a request for an initial home visit from *any* source. Needless to say, nursing service could not be continued without medical supervision of the patient, and effort is always made to secure medical orders before the first visit. But the fact that the insured person can request nursing service is very important and, in the first seven months' experience, the first request came from the family for 24 per cent of those who received nursing service.

Time does not permit further discussion of the many details of the plan, if I am to tell more of the story of our actual experience the first year. (A request to HIP, to Dr. Dean Clark, Medical Director, or to Miss Clara Richmond, who is the nursing consultant on the Medical Division Staff, will provide copies of all available material and answers to specific questions about the nursing service.)

As previously mentioned, the capitation rate was based on expected usage of services, with the understanding that this rate would be under constant scrutiny and subject to revision when sufficient experience was accumulated. It was estimated that a staff of 25 physicians in a medical group would be sufficient to provide an average of 7 physicians' services per person per year. According to the first year's experience, this estimate was high, but again it was considered advisable to plan for a maximum amount of service to allay all fears concerning the costs of this comprehensive program. What volume of requests for medical care would come from subscribers was an unknown factor.

I am indebted to the HIP Division of Research and Statistics for the following figures:

During its first year of operation, HIP had an enrollment which advanced from 2,643 on March 1, 1947, to 109,561 on February 29, 1948. Coverage was provided for a total of 701,299 months for subscribers and their dependents. These enrollee months are the equivalent of 58,442 enrollee years. For these insured persons, a total of 233,293 physician services were rendered. These services do not include radiologists' and pathologists' services nor any rendered by auxiliary personnel (office nurses, technicians. physiotherapists, etc.).

The physician services come to 4 per enrollee year. The nursing visits totalled 1,836 or 0.03 visit per enrollee year, (one nurse visit to about 127 physician services).

Of the 233,293 physician services, 30,511 were home visits of physicians. The nursing visits came to one per 16.6 physicians' home visits.

In the case of Medical Group "X", which is one of the HIP's most substantial medical groups with a high proportion of children in the enrollment and with excellent medical standards, the record shows 7,063 enrollee years and 189 nursing visits. This is a little less than 0.03 nursing visit per enrollee year. The physician services, as narrowly defined above, furnished by this medical group, came to 33,348 or 4.7 per enrollee year. There was one nurse visit per 176 physician services and one per 27 physician home calls.

A comparison with the original estimate for home nursing service, which you remember was deliberately set at a ceiling, shows that the nursing service given was only 1/10 of the amount estimated.

With the efforts made to send com-

plete information about nursing service available to each physician in the medical groups, and a list of nursing services sent to each subscriber, it was expected that the number of nursing services used would increase considerably as the year progressed, and as enrollment grew. This did not happen.

The kinds or types of home nursing service given to HIP patients compare favorably with the general programs of the visiting nurse associations in New York. Home nursing service for cancer patients, particularly following surgery, service for long-term illness, and giving of injections, especially penicillin, have been the most frequent services requested. Teaching of rehabilitation exercises following fractures have been requested for several patients. Less than the expected amount of maternity service has been requested, and for only two cases has the physician asked the nurse to teach the patient to give himself insulin for diabetes. The nurses taught, with the physicians' approval, several families to give injections to the ill member of the family and they also taught families how to give general nursing care to acutely ill patients who needed care throughout the day and night. The total figures for HIP service seem too small to be significant percentagewise.

There is no reason to believe there was dissatisfaction with the nursing service given, for no complaints were received and a few fan letters can be claimed. But there is reason to believe that some of the medical groups were concerned about the 10 cents of their capitation money which was set aside for nursing service. It is to be expected that this, as well as many other problems, may need to be discussed and changed as indicated. It may be that, for an experimental period, HIP will decide to pay for nursing service separately and not have it included in the medical group capitation. This would seem desirable. A nursing agency might also, for an experimental period, agree to accept a capitation payment, although this would require careful study to satisfy all groups concerned. It may also be advisable to carry out an experiment whereby a highly qualified public health nurse would work with one of the medical groups, preferably at a center connected with a teaching institution. Both the physicians and the insured persons may need a more specific outline of the functions which nurses should perform in the home and careful delineation of the circumstances under which nursing service should be requested by the subscriber. It is also important to establish more definitely the functions which nurses should perform at the medical group centers. Such an experiment would need a review with the doctors on a case by case basis, with knowledge of the needs of the patients and families for services which the nurse could provide.

But the most important point is a willingness to experiment. It will be a long time before we find the answers to all the unknowns unless we do experiment, and the appreciation of this fact by HIP is one of the reasons why it is of the greatest interest to our agency to participate in this health insurance plan. Another reason is the sincerity and high ideals demonstrated by the administrators of HIP and the social implications for the community. In a farsighted and progressive way effort is being made to establish for the workingman a means whereby a high quality of medical care can be provided through a prepayment health insurance plan.

Studies on Survival of Influenza Virus Between Epidemics and Antigenic Variants of the Virus*

R. M. TAYLOR, M.D., D.P.H.

International Health Division of The Rockefeller Foundation, New York, N. Y.

THE studies here reported comprise, first, surveys at approximately monthly intervals during the late fall, winter, and early spring for influenza virus in the throats of apparently healthy persons and of persons with upper respiratory symptoms; and second, a study of the antigenic characteristics of the strains isolated. Mention is also made of a limited experiment on human vaccination.

The surveys for virus were made in a state vocational school for boys. The boys were from 17 to 21 years of age and the number in the school ranged between 750 and 800. While for the most part they slept in individual rooms, they intermingled during meal, work and play hours. Sick call was held each morning and elevation of temperature was the customary criterion for hospitalizing those with respiratory symptoms and was also regarded as an essential feature for the clinical diagnosis of influenza.

Throat washings were secured by gargling 20 ml. of 2 per cent normal horse serum in a phosphate buffered solution. Following the morning sick call, throat washings were taken from those who at the time had acute respiratory symptoms and, in addition, from apparently healthy individuals selected at random, except as otherwise indicated. A total of 50 specimens, more or less, were collected at each visit. The bottles containing the washings were immediately iced, brought to the laboratory, and inoculated the same day.

At the laboratory the washings were pooled in groups of five, penicillin and sulfadiazine added to control bacterial growth, and 0.2 ml. of the pool inoculated into the amniotic sac of each of 6 chick embryos. Washings from persons with acute respiratory symptoms were inoculated separately or placed in the same pool. After incubating the embryos for 4 days at 35° C., the amniotic fluid and either the lung and trachea or sac membrane were harvested and pooled according to group. The sac membrane and lung and trachea were ground and suspended in the amniotic fluid. The suspension thus prepared was inoculated into a second group of normal eggs. The passages were thus continued until at least three passages had been completed. The agglutination of chicken erythrocytes was the test used for detecting virus.

Between November, 1946, and April, 1948, throat washings were collected on 15 occasions. These collections comprised 739 specimens, 716 of which were examined in pools of approximately 5 in each pool, making a total of 141 pools; and 23 specimens derived from persons with respiratory symptoms were individually inoculated.

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

Influenza virus was isolated from 4 of the 141 pools; one on February 27, one on April 1, and 2 on May 15, 1947. At the time of the first isolation (February 27) no recognized clinical influenza had occurred in the school since the beginning of the survey. Indeed, the first clinically diagnosed case did not occur until April 1, 32 days later. During the succeeding 3 weeks there were 31 boys who had symptoms usually ascribed to influenza. While the epidemic was active, influenza virus was isolated from pools of throat washings of symptomless persons and from 6 of 9 boys in the acute phase of the disease.

Examination of pools of washings collected 10 and 40 days following cessation of the epidemic failed to reveal the virus. In these latter pools there were purposely included throat washings from a number of boys who had suffered from an attack of influenza during the epidemic and from those comprising the pools in which influenza virus had been previously identified. Nor was virus detected in washings taken in November and December of 1947, and in January, February, and April of 1948. Since the 1947 epidemic, no illnesses have occurred which warranted a clinical diagnosis of influenza.

In brief, influenza virus was found in the throats of apparently normal persons 32 days prior to the onset of the clinically manifest epidemic and while the epidemic was active, but not on previous or subsequent occasions. Moreover, except during the epidemic, there was no detectable association of influenza virus with upper respiratory symptoms.

Two questions arise in connection with these findings: First, were the isolations legitimate, particularly the one made prior to the epidemic? It is felt that this question can be answered in the affirmative, because the egg passages were made in a laboratory wing where no other influenza virus had been introduced and because the strains isolated, as will appear later, were antigenically different from any laboratory strains then in our possession. Second, was the technique employed adequate to identify influenza virus if present in minute amount or if bound by the presence of antibodies? It is obviously impossible to give a categorical answer to this question. It may be said, however, that before undertaking the survey, several methods which had been described for concentrating influenza virus were investigated such as adsorption by charcoal, precipitation by alcohol, high speed centrifugation, adsorption and elution by chicken erythrocytes. Although further concentration of relatively low dilutions of virus suspended in a diluent free from foreign matter can be achieved by these procedures, no significant concentration of high dilutions of the virus in throat washings was consistently obtainable. Thus, efforts to concentrate virus in the pooled throat washings were abandoned. It was found, however, that the addition of concentrated heat-inactivated virus to a neutral serum-virus mixture, as described by McKee,[1] would, even in highly dilute mixtures, release some of the active virus, and this procedure was employed in examination of throat washings taken subsequent to the epidemic when humoral antibodies were more likely to be present.

Isolation of virus from persons with symptoms of influenza—During the epidemic period (March and April) in 1947, throat washings from 17 persons with acute respiratory symptoms were inoculated into embryonated eggs, as above described, and virus was isolated from 12. Six of the positive specimens came from the boys' vocational school, situated 130 miles north of New York City; 1 from a girls' school at Poughkeepsie, N. Y.; and the remaining 5 from New York City and vicinity. So far this year there has been no epidemic

NOTE: Initial serum dilution 1 to 32, and " O " signifies that there was no inhibition at this dilution. Four hemagglutinating units were used. All strains with exception of PR8, Lee, and Swine influenza had been isolated and passaged only in egg embryos.

in the boys' vocational school and no influenza virus has been isolated. But a strain was obtained in April of this year from one of two sick children in a family living in the suburbs of New York.

With one exception, all of these strains, as well as those obtained from the pooled throat washings, were readily adapted to growth in the allantoic sac after several amniotic passages. This exceptional strain, designated as 1233, will be referred to later.

The antigenic characteristics of the strains isolated—Immune sera were produced from several species of animals, including ferrets, hamsters, and rabbits. The ferrets and hamsters were immunized by intranasal instillation and the rabbits by intraperitoneal inoculation of allantoic or amniotic fluid of infected chick embryos. In some instances it was necessary to give hamsters a subsequent intraperitoneal inoculation to obtain an adequate immune response.

Hemagglutination inhibition—In performing this test, twofold dilutions of the serum were made and the virus antigen and chicken erythrocytes added in sequence. After standing 1 hour in the icebox, readings were made by the pattern method.[2]

Table 1 shows the result of cross-titrations with hamster immune sera. These titrations were made before the 1948 and other strains included in subsequent titrations were available. It will be noted that with the exception of strain 1233, the 1947 strains form a compact group and are quite different not only from the classical type strains (PR8 and Lee) and Swine influenza virus, but also from a 1943 A type strain (965). The lower titers obtained with Pool 52 and 63 strains may be attributed largely to the avidity factor, since antisera of these strains effectively inhibit all other 1947 strains save 1233. It will also be observed that 965 antiserum inhibits PR8 but that the reverse does not hold. The 1233 strain stands apart and appears to be immunologically unrelated to all of the other strains.

Table 2 reflects the results of titration with immune rabbit sera and includes, in addition to representative strains isolated in this laboratory in 1947, a strain FM1 isolated in 1947 from an influenza suspect at Fort Monmouth, New Jersey (received through the courtesy of Dr. J. E. Smadel), an Australian strain (CAM) isolated in 1946, and a strain (1265) isolated by us

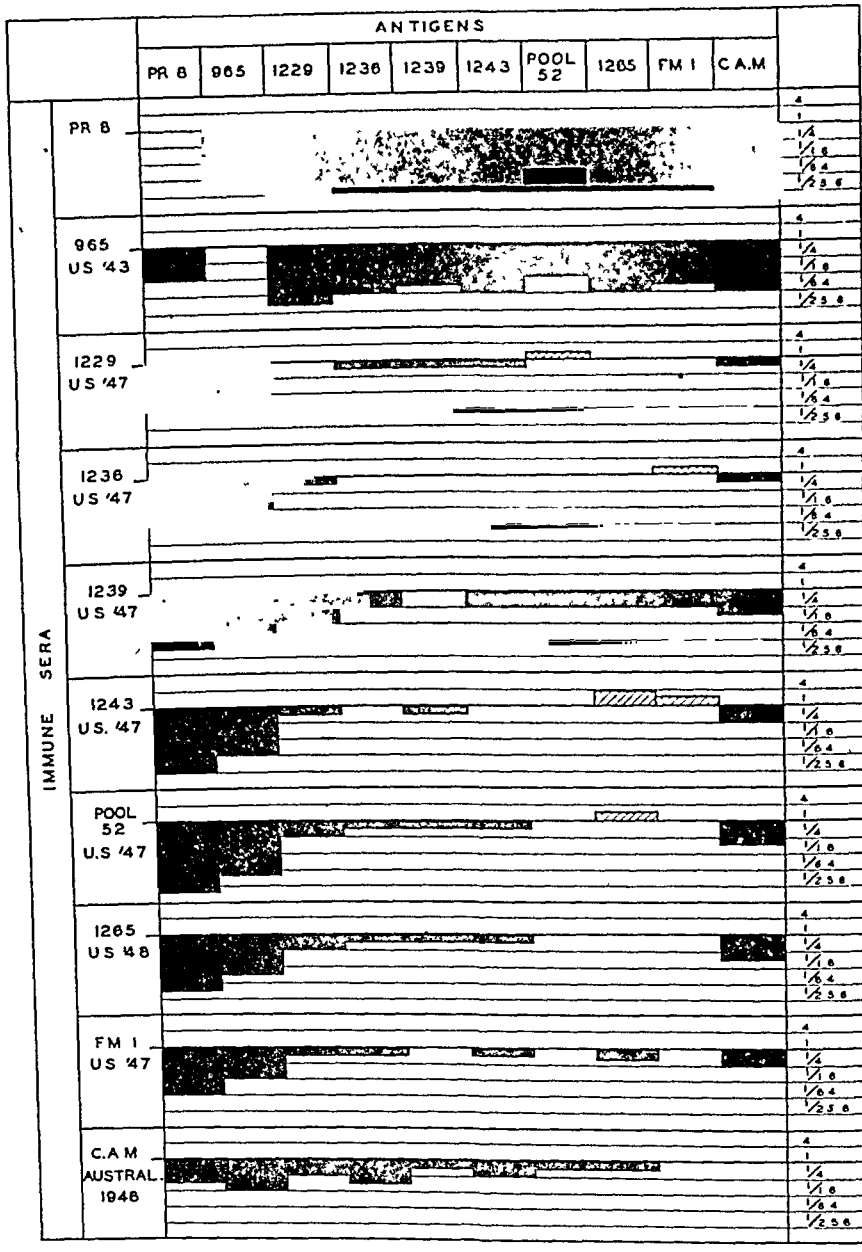

FIGURE 1—A Diagrammatic presentation of results of cross-hemagglutination titration shown in Table 2 after applying an avidity factor and dividing the product into the homologous titer which is assumed to be unity. The black columns below the base line represent the fractions obtained by dividing the heterologous titer into the homologous titer. The cross-hatched columns above the base line are indicative of heterologous titers which were greater than the homologous titer.

NOTE: Initial serum dilution 1 to 32, and "0" signifies that there was no inhibition at this dilution. Eight hemagglutinating units were used. All strains with the exception of PR8 had been isolated and passaged only in egg embryos.

in April, 1948. Again it will be seen that all of the 1947 strains are related with the exception of 1233. They are also closely related to FM1 and the 1948 strain (1265). It is of special interest to observe that the Australian strain (CAM), though differing somewhat, appears to fall into this group. Certainly it is more closely related to the 1947 strains than the 1943 strain.

These differences and relationships become clearer if an avidity factor, as recommended by Hirst,[3] is applied and the product divided into the titer of the homologous serum which is assumed to be unity. The results are illustrated in Figure 1. Strain 1233 is not included in this figure, since there was no cross-immunity whatsoever between this and the other strains tested. Similar results were obtained with the *in ovo* neutralization test.

When, however, the hemagglutination inhibition test was applied to acute and convalescent phase human sera, the relationship of the virus producing the epidemic in 1947 to PR8 became evident. All of 15 persons from whom acute and convalescent phase sera were obtained showed a rise in titer to PR8 following the influenzal attack, although the rise was not so great as to a 1947 epidemic strain.

The broader immune response of adult human beings as compared to animals is probably due to previous conditioning with type A virus infections. Indeed, this may be demonstrated in animals. Ferrets and hamsters infected, first with PR8, and after an interval infected with a 1947 strain, show a further rise in antibodies to PR8 following the second infection.

Complement-fixation — The complement-fixation reaction is generally recognized as being less strain-specific than hemagglutination inhibition and is therefore useful in demonstrating kinships rather than minor differences. Yet, as will be observed from Figure 2, there is a marked difference between PR8 and the 1947 and 1948 strains. The 1943 strain (965) appears to lie between the two.

Human vaccination experiment—At the time the epidemic occurred in the vocational school there were 176 boys who had received 4 months previously a mixed A and B type commercial influenza vaccine and 601 who had not been vaccinated. The attack rate among the vaccinated was actually

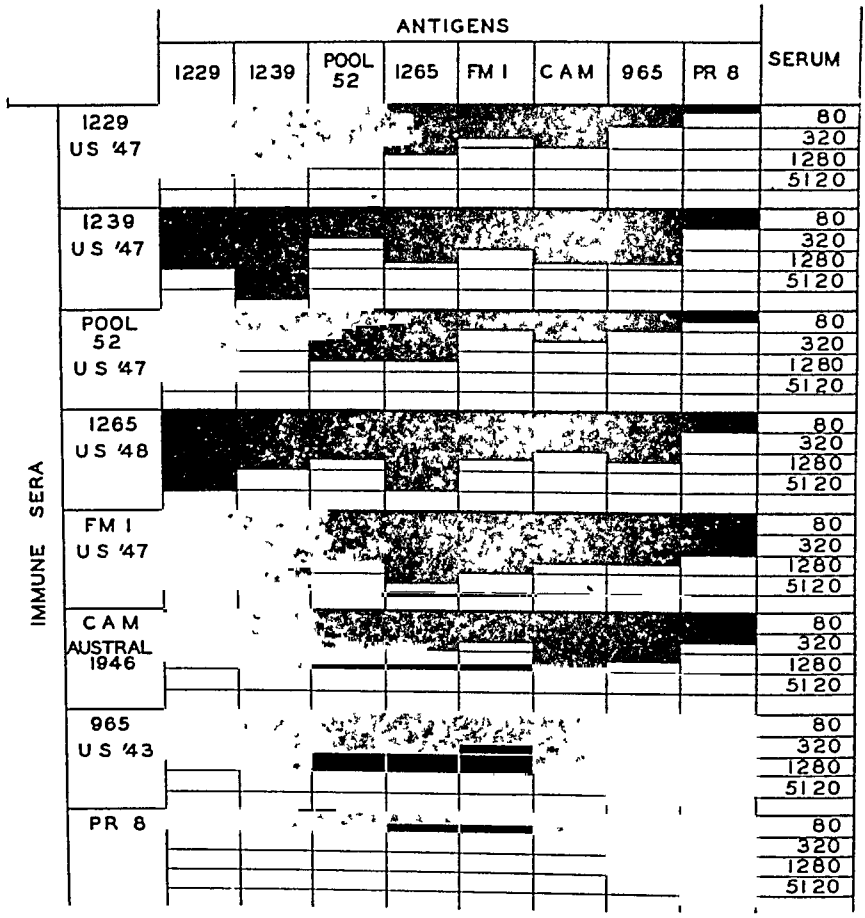

FIGURE 2—A diagrammatic presentation of complement-fixation titration of immune ferret sera The black columns below the base line indicate the dilution of the serum shown in the column to the right at which fixation of complement occurred

One and one-half units of guinea pig complement were used in these tests Whole allantoic fluid, appropriately diluted, was employed as antigen.

higher (6.3 per cent) than among the unvaccinated (3.3 per cent). The difference is not statistically significant, but certainly there is no suggestion that the vaccine afforded protection.

The 1233 aberrant strain — This strain is still under study and a more complete description of it will be published later. Suffice to say here that it was isolated in March, 1947, from the throat washings of a man living in New York City. At the time the throat washings were taken, he had a mild headache and backache and coryza which persisted for only 24 hours. Unfortunately no acute-phase blood was taken, but blood specimens secured 1, 3, 6, and 12 months following the attack showed a progressive fourfold and eightfold drop in the hemagglutination and complement-fixation titers respectively to this strain. There was no significant alteration in titer in these series of sera to either A or B type influenza viruses.

Cross-titration by hemagglutination

and complement-fixation of immune animal sera has shown no immunological relation of strain 1233 to A and B type influenza viruses. Nor has the examination of acute and convalescent human sera from known A and B type influenza shown a rise in antibodies to this strain. With the exception of two of three acute and convalescent phase sera received from Venezuela and obtained from persons who had an upper respiratory illness, we have not so far encountered any other respiratory infection which has produced an immune response to this strain.

Besides its unique antigenic characteristics, it is peculiar in other aspects. It has been exceedingly difficult to adapt to growth in the allantoic sac and to this extent it resembles some of the B type strains. Although it agglutinates chicken erythrocytes, its behavior in this respect is erratic.

Hamsters, ferrets, and monkeys develop antibodies following intranasal inoculation. The strain has been carried through three passages in ferrets by transfer of nasal washings, but repeated attempts to establish it in mice have failed.

It would seem to belong to the influenza group of viruses, since it agglutinates chicken erythrocytes, agrees approximately in size, and like them is pneumotropic, since it produces lung lesions in chick embryos and infects hamsters, ferrets, and monkeys by intranasal inoculation. It is serologically unrelated to mumps and Newcastle disease viruses.

DISCUSSION

The only significant positive finding revealed in the surveys for influenza virus is that the virus may exist in a limited compact population for at least one month before giving rise to definitely recognizable clinical manifestations. That the virus was found in the throats of symptomless persons during the epidemic is not surprising, and offers further evidence of the general dissemination of the virus during such episodes. The failure to discover virus except shortly before and during the epidemic suggests that the circulation if not the sojourn of the virus in this institutional population was of limited duration. This would tend to support the view that the virus is maintained by a chain of silent or manifest infections and is not continuously harbored in a limited and more or less stabilized human population.[4, 5]

The occurrence of virus variants or mutants is not only of genetic interest but also of considerable practical importance. Minor variations in type A influenza strains have long been observed and may in part be attributed to passage in laboratory animals, but the deviation of the 1947 strains, as here noted and previously reported by others,[6-11] is of such magnitude as seriously to complicate the control of the disease by vaccination. Several questions require answering. Among these are: (1) Are the number of variants finite or are they constantly developing and thus perhaps infinite in number and unpredictable in their appearance? (2) What are the factors which influence their development? (3) What deviation from the norm of the A and B types is of public health significance, and what should be the methods and criteria for recognizing such deviation? (4) What feasible steps can be taken to recognize expeditiously the appearance of a new variant?

It seems to us not improbable that variants are constantly developing and that when one which is sufficiently virulent and different from preëxisting strains encounters a relatively susceptible population, widespread infection is likely. In this connection the similarity of the strain isolated in Australia in 1946 to those found in this country in 1947 and 1948 is of interest.

There are probably many factors which influence the development of variants. For example, it has been noted that repeated passage through laboratory animals may produce changes in the antigenic qualities [12] and Dr. A. Saenz and Dr. J. A. Kerr, working in these laboratories, have found that one of our 1947 strains, after a number of passages in embryonated eggs in combination with homologous immune sera, had veered antigenically from the parent strain. It is thus conceivable that the natural passage of influenza virus through human subjects where antibodies are encountered as the result of previous infections may give rise to strain deviation.

We now have at our disposal a number of methods of varying sensitivity for detecting immunological differences among influenza virus strains. But it may be questioned if our experience is as yet sufficient to establish exact criteria for determining the magnitude of the deviation from the type norm that is of practical significance.

The aberrant 1233 strain, though differing markedly from all other influenza strains with which it has been compared, may prove to be of little public health import, as so far it has been linked to only two cases of respiratory infection other than of the person from whom it was isolated.

As to the expeditious recognition of new strain variants, the move to create a World Influenza Center with appropriately situated sub-centers for collecting information and material and for either classifying strains supplied by other laboratories or distributing standardized immune sera and antigens would seem to be a step in the right direction.

SUMMARY

1. A search for influenza virus in an institutional population during the fall, winter, and spring months revealed the presence of virus in the throats of symptomless persons 32 days preceding a clinically manifest epidemic and during the epidemic but not on other occasions.

2. All save one strain isolated from influenza suspects in 1947 and 1948, as well as the strains isolated from the throats of symptomless persons shortly preceding and during the epidemic of 1947, are antigenically similar. They are also antigenically related to a strain (CAM) isolated in Australia in February, 1946. While they may be regarded as belonging to type A influenza virus, they differ markedly from PR8 and an A type virus isolated in 1943.

3. There was no significant difference in the influenza attack rate among persons vaccinated with a commercial A and B type influenza vaccine 4 months preceding an institutional epidemic in 1947 than among those who were not vaccinated.

4. Reference is made to a respiratory virus strain isolated in 1947 which appears to be antigenically unique.

Comparison of Pertussis Cultures by Mouse Protection and Virulence Tests*

P. L. KENDRICK, Sc.D., F.A.P.H.A., ELAINE L. UPDYKE, Sc.D., AND GRACE ELDERING, Sc.D., F.A.P.H.A.

Bureau of Laboratories, Michigan Department of Health, Western Michigan Division, Grand Rapids, Mich.

THE successful use of intracerebral infection in mouse protection tests of pertussis vaccine [1, 2] has called attention to a new method for measuring the virulence and protective properties of single cultures of *Hemophilus pertussis*. The practical value of such a study is apparent in relation to the criteria for selection of cultures for vaccine preparation. In the present study, the object has been to rank a group of cultures according to virulence and according to mouse protective properties, and to determine whether any correlation could be found between the two characteristics.

CULTURES FOR STUDY

A group of 76 cultures of *H. pertussis* (70 smooth and 6 rough) were tested for virulence; 41 of these (36 smooth and 5 rough), also for mouse protection. In addition to pertussis cultures, 33 parapertussis cultures were tested for virulence, 2 of them for protection against *H. pertussis;* and 4 bronchiseptica strains were tested for virulence, one for mouse protective properties.

Source and maintenance of cultures

Of the 70 smooth pertussis strains, 55 were isolated in Grand Rapids from routine diagnostic cultures; 10 were received from England, 2 from Mexico, 1 from Australia, and 2 from New York. The 6 rough cultures were old stock strains received from other laboratories where they had been carried for years on various laboratory media, some of them with isolation dates as early as 1916. The 33 parapertussis cultures included 19 isolated by our own laboratory, and 14 were from England, Mexico, and various places in the United States. Three of the *Br. bronchiseptica* cultures were from rabbits and one from a child.

Since 1939, cultures have been dried from the frozen state, the newly isolated ones within 6 transfers from the original plate. Two smooth strains of the study group, S5 and S160, with isolation dates in 1932 and 1933, respectively, were transferred on Bordet-Gengou medium at monthly intervals until 1939, when they were lyophilized.

For study, the cultures were revived from the dried state on Bordet-Gengou medium, and used within six subcultures. Division into rough and smooth strains was made on the basis of growth characteristics, colony appearance, production of hemolytic zone, and morphology of the organisms in stained preparation. According to these generally accepted criteria the cultures included for study were classified as either smooth or rough; intermediate strains were not available.

The cultures were tested for agglu-

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

Sponsored by the Subcommittee on the Evaluation of Administrative Practices of the A.P.H.A. with the aid of funds granted by laboratories in the Biologic Section of the American Drug Manufacturers Association.

tinability using the rapid technique described in *Diagnostic Procedures and Reagents*,[3] and a single antiserum prepared against culture 18-323, the strain used for infection in the mouse protection tests. The agglutination tests were used to check the identity of the cultures and were not intended as a detailed serological study. As was expected, the rough strains were not agglutinated. However, an unexpected variation in agglutinability was observed among the 64 smooth cultures. Although it has been rather generally accepted that smooth cultures of *H. pertussis* form a serologically homogeneous group, it was found that only about half of the cultures tested had titers in the range of the homologous strain which varied around 1:10,000. Eighteen were agglutinated in the range 1:2,000 to 1:5,000; and 11 to low titer only, that is, 1:200 to 1:1,500. These findings suggest the need for further serologic study.

TESTS FOR VIRULENCE

The virulence of pertussis cultures probably has been tested most frequently on the basis of intraperitoneal injections of mice with mucin suspensions. The large killing dose (1 to 3 billion) and the lack of an incubation period, limit such a test to relatively rough determinations. The comparatively small doses of virulent cultures required to kill mice infected by the intracerebral route, and the fact that the incubation period between injection and the first symptoms suggested a true infection, offered promise for a more sensitive virulence test.

Virulence test procedure

Fifteen white mice in the approximate weight range of 16–20 gm., are used for each culture, five mice for each of three graded doses 10^3, 10^5, and 10^7. The culture is grown for 24 to 30 hours on Bordet-Gengou medium plus peptone and the growth harvested into 1 per cent casamino acid. The suspension is adjusted to 5 bil. organisms per ml. by photometric methods and the necessary dilutions made in 1 per cent casamino acid to make the required dose in a volume of 0.03 ml. The mice are injected intracerebrally under anesthesia within 2½ hours after the culture has been harvested.

The endpoint is defined as the least dose that kills the majority of a group of mice within 14 days. Deaths during the first 48 hours are considered as due to injury, and if any such occur in a group of 5 mice, that group is considered unsatisfactory for establishment of the endpoint. It may be mentioned that the limits of the testing range were suggested by many preliminary tests. Smooth strains appeared to be included in the range ending with 10^7. Observations in a higher range were limited by the number of organisms that could be injected into a mouse's brain as an infective dose, without causing early death with toxic symptoms.

To obtain a more precise measurement of the virulence, a test is performed with larger groups of mice, in the range indicated by the first test. For example, if the endpoint with a particular culture is 10^3, a further test with 30 mice divided into 3 groups and injected with doses 80, 400, and 2,000 respectively, will usually establish the LD/50 of the culture.

Results of virulence tests

The results of intracerebral virulence tests with 70 smooth and 5 rough strains of *H. pertussis*, 33 parapertussis and 4 *Br. bronchiseptica* cultures are summarized in Table 1.

The cultures fell roughly into two groups with respect to their virulence. Of the 70 cultures classified as smooth, 55 or approximately 80 per cent, were less virulent and required the larger doses of 10^4 to 10^7; 15 or approximately

TABLE 1

Results of Virulence Tests: Summary

	No. of Strains with Endpoints * as Indicated			
	10^3 or Less	10^5 to 10^7	No Virulence at 10^7	Totals
H. Pertussis				
Smooth	15	55	0	70
Rough	0	0	5	5
Parapertussis	0	2	31	33
Br. bronchiseptica	3	1	0	4
				112

* Endpoint is defined as the least dose that kills the majority of a group of mice.

20 per cent required a dose of only 1,000 or fewer organisms to kill the majority of a group of mice. In tests for the LD/50 of these 15 cultures, their endpoints were found to range from approximately 100 to 1,000.

Of the 33 parapertussis cultures tested, 31 were not virulent in the range including 10^7, and 2 had an endpoint of 10^7. Four cultures of *Br. bronchiseptica* were tested and all were virulent, 3 of them in the smaller doses.

MOUSE PROTECTION TESTS

Procedure

The procedure for a mouse protection test, using the intracerebral route for challenge, has been described previously.[1] Briefly, for each antigen tested, 44 white swiss mice, 13–16 gm., sexes equally divided, were given a single injection intraperitoneally. Four groups of 11 mice each received graded doses, such as 0.06, 0.3, 1.0 and 1.5 bil., respectively, and after a rest period of 10 days they were injected intracerebrally with a challenge dose of approximately 50,000 organisms as determined photometrically. This dose was in the approximate range of 100 to 200 times the LD/50 dose of the challenge culture 18-323. In each experiment there was included a similar group of mice injected with graded doses of a reference antigen and also an unimmunized group of mice for checking the LD/50 and test dose of the challenge culture. At the time of injection of the mice, cultures on Bordet-Gengou medium were made for colony counts as a check on viability. After a 14 day observation period, the results of the test were summarized in terms of dead and surviving mice, and analyzed by the method of Litchfield and Fertig[4] using the table published by Weiss.[5]

All tests of antigens prepared from individual cultures were included in the data with the exception of those which for some particular reasons were unsatisfactory. An individual test was excluded from analysis if the response to immunization was not in proportion to the graded dosage; or if it was not possible to fit a line to the plotted points with reasonable accuracy. All tests in a particular experiment were excluded if the reference antigen and two or more test antigens had exceptionally high endpoints or poorly graded responses. Also, in tests with only three graded doses in which the smallest dose protected none and the largest dose protected all of the mice, no endpoint could be established even though there was evidence of protection, and the antigen was retested with a different dosage schedule.

In addition to the 36 tests tabulated for the vaccines prepared from the smooth cultures, 5 tests were not analyzed for one or another of the reasons stated. Also, antigens from 2 other cultures were omitted from analysis because none of their tests was satisfactory for analysis.

Protection tests with smooth strains of H. pertussis

Based on the results of single tests, always in experiments which included a reference antigen and other test antigens, the ED/50's of the vaccines prepared from the 36 single cultures were as listed in Table 2.

TABLE 2

ED/50's in Mouse Protection Tests with Vaccines Prepared from 36 Smooth Strains of H. Pertussis

0.05	0.15	0.25	0.33
<0.06	0.16	0.26	0 43
<0.06	0.17	0.26	0 43
0.06	0.18	0.29	0 46
0.06	0.19	0.30	0.48
0.07	0.20	0.30	0 51
0.12	0.20	0 30	0.52
0.14	0.22	0.30	0 61
0.15	0.23	0.33	>1.50

Median = 0.24

1st Quartile = 0.15 3rd Quartile = 0.33

Variations in protective properties were observed among the 36 cultures, as was expected. The whole range of results is from 0.05 to 1.5 billion, the median is 0.24 billion and the middle 50 per cent between 0.15 and 0.33. In order to judge the significance of observed differences in protective properties it is necessary to know what variations may be expected to occur from test to test. Light is thrown on this question by the results of 45 different tests of vaccines prepared from culture 10-536 (the reference antigen used for the previously published comparative tests[1] and for 18 of the tests of the 36 single culture vaccines in this study).

In the ED/50's listed in Table 3 the median is 0.23 billion and the middle range is 0.16 to 0.38. Each of the 36 single culture antigens in Table 2 might be expected to show a similar distribution about its respective endpoint.

Because of the distribution of ED/50 values of the 36 smooth cultures in relation to the median of the tests with the single culture 10-536, it is probable that most of the cultures are not very different in protective properties from 10-536. However, those with the lowest ED/50's suggesting better protective properties form a group for further study in repeated tests in the search for superior cultures for vaccine production. Already repeated tests have been done on some of these cultures.

Protection tests with rough pertussis strains and with related cultures

Mouse protection tests with antigens prepared from 5 rough cultures of *H. pertussis* demonstrated no protection. Vaccines prepared from two parapertussis cultures also provided no protection against *H. pertussis* infection. One bronchiseptica culture vaccine appeared to provide slight protection against pertussis infection. Further cross-protection tests are planned.

Correlation of endpoints of virulence and protection tests

If the 36 cultures of smooth *H. pertussis* with their protective endpoints are classified according to the results of their virulence tests, it is found that 11 were in the virulence group with LD/50 values of 10^3 or less, and 25 in the virulence group with endpoints of 10^4 to 10^7. Four of the 11 more virulent and 14 of the 25 less virulent strains had protective ED/50 values about the same as or lower than the

TABLE 3

ED/50's in 45 Mouse Protection Tests with Vaccines Prepared from Culture 10-536

0.15	0.23	0.38	1.10

0.23 (Median)

1st Quartile 0.155 3rd Quartile 0.385

median value (0.24 billion) for the 36 cultures; that is, the values were in the direction of better protection.

It is evident that there is a lack of association between relative degrees of virulence and protective properties of the 36 smooth strains in which the killing dose ranged from 10^2 to 10^7. In contrast, the 5 rough cultures of *H. pertussis* were found to be without either virulence or protective properties.

DISCUSSION

The results of the comparative tests in this study can scarcely be considered without raising the question of their bearing on the selection of strains for the preparation of pertussis vaccine. Until a practical mouse protection test became available, the only criteria that could be used were identity tests for smooth strains, and some rough test for laboratory animal killing properties. The use of strains rather recently isolated, or kept in the dried state since isolation, has been a precaution in line with the effort to use smooth antigenic cultures. Also several strains instead of one have been used to allow for possible unknown variations in antigenicity. With the availability of a mouse protection test, there seems to be a sounder basis for selection, even though we recognize that mouse protection cannot be translated directly into terms of child protection.

As might have been expected, the 5 rough strains tested were non-protective. Among the 36 smooth cultures, the variations in ED/50's of the majority were within a relatively small range, suggesting that in general a culture with smooth characteristics would have protective properties. The variations do point out a small group of cultures for further study in repeated tests to determine whether the low ED/50's represent a true superiority in protective properties.

In relation to vaccine production the experimental data presented emphasize the need for the greatest care in the selection and maintenance of smooth strains, and suggest an approach to the study of other factors.

SUMMARY AND CONCLUSIONS

Virulence

A mouse virulence test for cultures of *H. pertussis*, using intracerebral injection of the infective dose, has been outlined.

Of 70 smooth strains of *H. pertussis*, all showed virulence within the range of the test which employed test doses of 10^3, 10^5, and 10^7; 6 rough strains did not show virulence.

The 70 smooth strains fell roughly into groups of greater or lesser virulence; approximately 20 per cent were in the more virulent group and killed the majority of a group of mice in an intracerebral dose of 1,000 or fewer organisms.

Of 33 parapertussis cultures, only 2 showed virulence in the highest dose tested; the others did not. The 4 bronchiseptica strains were all virulent, 3 of them in the more virulent range.

Protective properties

The mouse protective ED/50's of vaccines prepared from 36 single cultures have been listed and the results evaluated in the light of 45 different tests of reference antigen 10-536. Single tests have indicated a group of cultures for further study in repeated tests in the attempt to find superior strains for vaccine production.

Vaccines prepared from 5 rough strains of *H. pertussis* and 2 strains of parapertussis gave essentially no protection; one strain of *Br. bronchiseptica* gave very little protection.

Correlation of virulence and protective properties

The 5 rough strains tested were non-

virulent and also non-protective when used in vaccines in mouse tests.

Among the 36 smooth strains tested there was no quantitative correlation between virulence and mouse protective properties.

Short Course in Sewage and Industrial Waste Disposal Problem

The School of Public Health, University of Michigan, announces a 2 day short course to be given at the request of the Michigan Sewage Works Association. It is designed to meet a need indicated by the Association for a comprehensive technical review, analysis, and interpretation of the basic scientific considerations involved in problems of sewage and stream pollution. The course is presented especially for the benefit of the scientific worker of industrial and official agencies involved in sewage and industrial waste disposal. Registration is $5, through the School of Public Health, Ann Arbor, Mich.

The Diphtheria Epidemic in Amsterdam

A. CHARLOTTE RUYS, M.D., AND A. L. NOORDAM, M.D.

Municipal Public Health Service, Amsterdam, Netherlands

I. Spread of the Disease; Significance of Types

BEFORE 1939 diphtheria in the Netherlands was rare, in contrast to the German territories bordering the Dutch frontier where a severe epidemic raged. The first increase of diphtheria in the Netherlands was noticed in 1938–1939 in the south-eastern provinces near the German border. However, there was little diphtheria elsewhere in the country. In May, 1940, the Netherlands were occupied by the German armies, and contact of Dutch people with Germans became more frequent. Table 1 shows diphtheria morbidity in the Netherlands as a whole, and separately in Amsterdam, beginning with 1918, in which year diphtheria was more prevalent than it had been at any time since 1900. In 1944–1945 the data for the country as a whole were less reliable than those for Amsterdam because the south and middle parts became war territory. In Amsterdam, reporting continued and all cases were controlled by the public health authorities.

FREQUENCY OF THE VARIOUS TYPES OF DIPHTHERIA BACILLI IN AMSTERDAM

In July, 1939, typing became part of the routine work in public health laboratories. Till September, 1940, we isolated among the Amsterdam patients only mitis strains with the exception of two atypical gravis strains and one intermedius strain. However, among a group of 96 German Jewish refugee children in September, 1939, a diphtheria epidemic broke out of such a severe character as had hitherto been unknown in Amsterdam. From 26 patients 20 strains of diphtheria bacilli were cultivated, all of which belonged to the typical gravis type. The children were rigorously isolated and no con-

tacts with the Dutch population occurred.

After September, 1940, several intermedius infections were diagnosed. The first cases were contacts of children who had returned from Austria. The disease did not assume an epidemic form and in the following months only isolated intermedius infections were found, many of whom were in German contacts.

After August, 1941, the first gravis cases in Dutch people were seen. These were practically all in German contacts. No cases were reported as developing from contact with people in the southeastern provinces. The gravis infections caused a severe form of the disease; often many patients in one family were ill and several died, but the disease remained confined to immediate contacts. This situation lasted till the summer of 1942, when all at once in August, the epidemic spread like fire among the population. In the first half of the year, 123 cases were reported; in the second half, 1,075. Table 2 gives the number of families infected with the various types in the first war years.

The prevalence of all types increased, but infection with intermedius and gravis strains constituted the larger part of the rising epidemic. Mitis infections were distributed evenly over the whole city and remained so during the epidemic. It appears, therefore, that a small number of imported cases may have been responsible for the increasing prevalence of gravis and intermedius types. Intermedius and gravis infections, however, which first were irregularly scattered, in the sudden increase in 1942 became mainly localized in certain foci. These foci were noted especially in those regions where dwelling conditions were poorest. As the epidemic continued, gravis and intermedius types also spread over the whole city.

At the height of the epidemic, all strains isolated during one month were typed. In 1944, this became impossible owing to the very severe restrictions. Only starch fermentation was

* "Large families" had more than 3 children of 0–15 years; "small families" 3 or less.

tested, but this gave an approximation of the percentage of gravis infections.

When the epidemiology of the various types were studied separately it became obvious that gravis and intermedius types were more aggressive than mitis strains. From 11 patients who, in spite of a negative Schick reaction, got diphtheria, we isolated only strains of the intermedius (3 times) or gravis types (8 times), but never mitis strains. We also noted a healthy carrier of the mitis type who acquired typical gravis diphtheria after contact with gravis carriers.

In a home for boys between 10 and 18 years old a diphtheria epidemic broke out. A culture survey of the 92 inmates showed intermedius and mitis carriers; among the latter both avirulent, and virulent strains. The 32 patients, however, suffered from intermedius diphtheria. None was infected with a mitis strain.

In families, patients infected with gravis and intermedius strains were the origin of more secondary cases than were patients with mitis infections, as is shown in Table 4.

In both large and small families the intermedius and gravis types were found in multiple familial cases nearly twice as often as the mitis type.

SUMMARY

The diphtheria epidemic in Amsterdam seemed to be caused partly by the importation of gravis and intermedius strains from Germany. However, the peak of the epidemic was delayed for two years after first contacts with Germans. The prevalence of mitis type increased after 1941, but was overshadowed by the other types in 1943. Later the mitis type was responsible for nearly half of all cases. Gravis and intermedius strains were more aggressive than the mitis type, but not always the most lethal.

II. Case Fatality Rate; Age Distribution; Schick Reactions

Fatality rates. In the Amsterdam diphtheria epidemic (1942–1947), just described, the case fatality rate was never high, despite the fact that many cases were caused by intermedius and gravis strains. At the height of the epidemic (1943–1946), the fatality rate was lower than in the beginning and in the end (Table 5).

The very poor nutrition of the population at this time seems to have had no influence. In the years of most extreme famine (1944–1945) in all age groups except the infants, lethality was lower than in the year when the epidemic began (1942) when nutrition was still adequate. Even the scarcity of therapeutic serum in those years seems not to have led to a higher lethality.

The high mortality among infants in 1945 coincides with an exceptionally high general infant mortality. The

TABLE 5

Case Fatality Rate of Diphtheria in Amsterdam

Year	Number of Cases	Lethality (Per cent)	Year	Number of Cases	Lethality (Per cent)
1930	642	1.7	1940	99	4.0
1931	482	2.9	1941	169	3.5
1932	617	2.7	1942	1,367	4.9
1933	588	2.0	1943	7,687	3.5
1934	342	2.3	1944	7,932	2.3
1935	132	3.0	1945	5,588	3.5
1936	83	3.6	1946	3,823	3.2
1937	66	3.0	1947	1,265	5.0
1938	128	6.2			
1939	79	1.3			

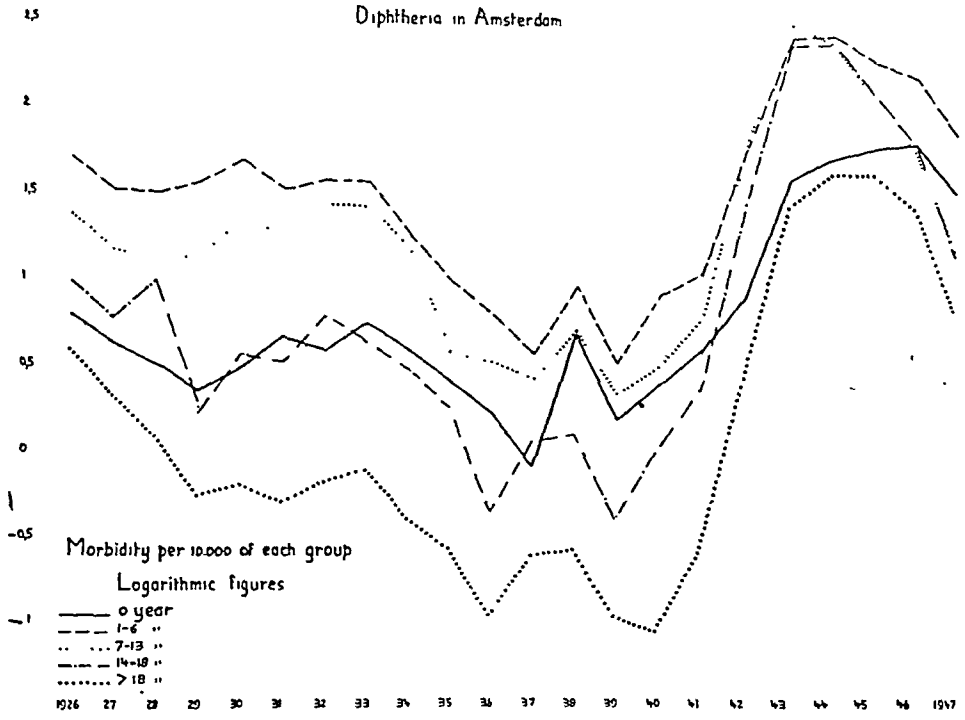
number of infants suffering from diphtheria was always relatively low. Percentages therefore have less value than in other age groups.

A certain number of false reports of diphtheria were made to deceive the Germans, but the public health nurses who visited the homes kept our own records accurate. This is evident from the fact that in a certain period in 1943, the lethality of all cases in our records (2,019) was 3.1 per cent. In 1,380 of these, diagnosis was confirmed by pure cultures, which had been typed. In this group the lethality was 3.2 per cent, which is practically the same.

The lethality of 487 cases of gravis infection in 1942 was 7.5 per cent. In 1943 it had dropped to 4.6 per cent of 2,325 cases (typed by means of a positive starch fermentation); a difference of 2.9 ± 1.3 per cent. The lethality of 2,114 intermedius and mitis patients together (starch fermentation negative) in 1943 was 1.4 per cent, in 1942 it had been 2.5 per cent of 369 cases; a difference of 1.1 ± 0.8 per cent.

Age distribution. In the course of the epidemic the age distribution of cases changed considerably, showing a shift to older age groups (Tables 6 and 7).

The same phenomenon has been observed in several other parts of Europe (Ipsen in Copenhagen,[2] Walker in Germany,[3]) and has been ascribed to the effect of the immunization of large numbers of children, in contrast with the adults who were not immunized.



However, other factors also influence age distribution of diphtheria. Percentages give no real insight into this problem because they are interdependent. We therefore have made curves of the logarithms of the morbidity figures in each age group (Figure I). From the beginning of the epidemic there has been an enormous spread of diphtheria bacilli, especially among children. In 1943–1944, morbidity rates reached their peaks in all age groups between 1 and 18 years. Most of those who escaped illness were already immune or became spontane-

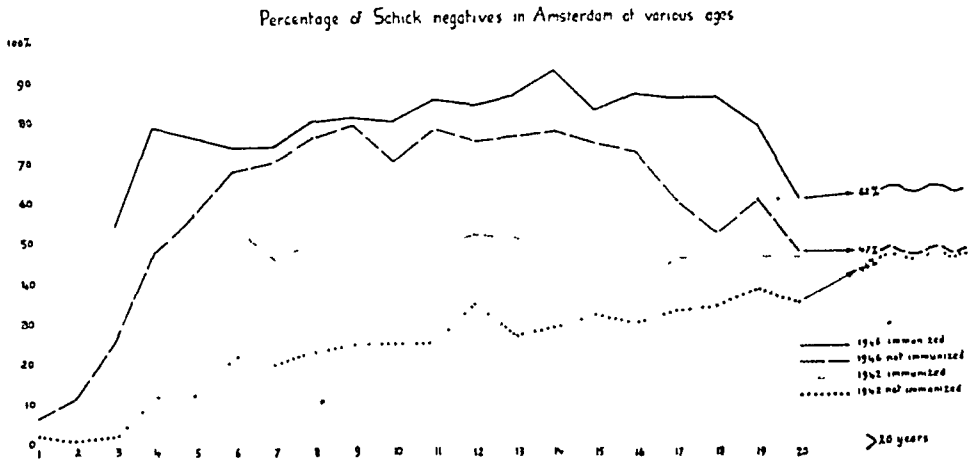
FIGURE I

ously immunized. In the following years this resulted in a decline in morbidity rate in the 1–18 years group because there were only a few susceptibles left. This process was most rapid in school children (7–13 years) among whom the spread of diphtheria bacilli was greatest. That the spread of diphtheria bacilli, however, did not immediately diminish, is evident from the continued high morbidity rate among infants, the curve of which does not fall before 1947.

We assume that the spread of diphtheria bacilli among adults was from the beginning less intensive. It was longer, therefore, before the susceptible adults became ill, and spontaneous immunization was much less frequent. In addition, because of the extremely low morbidity in the preceding years, few had become immune, with the result that there was a continued high morbidity rate among adults.



Schick reactions. The Schick rates at the various ages, determined in 1942 and 1946 and which will be discussed later (Figure II), are in accordance with the above surmise. Evidence for the intensive spread of diphtheria

FIGURE II

bacilli among school children is seen in the high percentage of Schick negative children (6–9 years) who did not suffer from the disease although not immunized (1946).

Immunized children of the same age suffered only slightly less morbidity. We infer that immunization had relatively little influence on the age distribution of diphtheria in this outbreak. This opinion is strengthened by the observation that in a former diphtheria epidemic (1917–1921) before immunization was general, the same shift to older age groups was observed, although in a lesser degree. Likewise, in the scarlatina epidemic (1941–1945) when no immunizations against this disease were performed, the same phenomenon was observed. Then, also, a shift to the older age groups was seen.

Among the adults more women than men suffered from diphtheria. In 1942, in the 14–18 years group, 66 per cent were women; in the group 18 years and older, 72 per cent. In 1943 these figures were 57 and 74 per cent, respectively. In the younger groups there was no difference. This may be due to a more frequent exposure of the adult women because of their more intensive contact with children.

In the beginning of 1942, before the epidemic broke out, a survey of the susceptibility of the Amsterdam population was made by means of the Schick reaction in a group of 5,763 non-immunized and of 2,026 immunized people. In 1946, when the epidemic was subsiding, a new survey was made in 3,815 non-immunized and 2,990 immunized people. The results of these surveys are summarized in Figure II. The nature of these data can be ac-

FIGURE III

counted for by assuming an intensive spread of diphtheria bacilli among the younger age groups and a less frequent exposure to diphtheria bacilli in the older age groups, in which natural immunization is less frequent. In addition, a conversion of the negative Schick reaction into a positive one, especially prominent in the groups less exposed to contamination, must occur. Figure II also shows that even in the years of the famine (1944–1945) immune processes must have been fairly active; otherwise such a high percentage of Schick negatives would not have been attained. However, we are well aware that antibodies alone do not determine the resistance against diphtheria bacilli; numbers of Schick-positive persons become Schick-negative without having suffered from the disease.

The Schick-negative rate, which is the same for both sexes in the youngest groups, showed a difference at school ages. In groups of various economic status the girls of 6–14 and 17 years always had a lower Schick-negative rate than the boys of the same ages. In 1942, of 744 boys (6–17 years old) 30.5 per cent were Schick-negative; of 719 girls, 23.8 per cent; a difference of $6.7 + 2.3$ per cent.

In the preschool ages, figures for both sexes were the same and in those older than 30 years there was a higher percentage of Schick-negative reactors among women than among men.

These observations can be accounted for by a relatively larger Schick conversion rate from positive to negative among females than among males, which in the older age groups, is counterbalanced by the greater contact of women with infected children.

In infants of 0–6 months the Schick reaction is often negative, even when the mother is Schick-positive herself (3 of 11 cases observed). So the skin and mucous membranes seem not to react in the same way at the various ages. Cellular immunity probably plays an important part. This is borne out by the studies of Frobisher, Parsons, Updyke, etc.[5, 6]

We saw in a home for unmarried mothers an infection with a gravis strain imported by one of the mothers who suffered from a very severe faucial diphtheria from Germany. Fourteen infants were infected but none showed the symptoms of typical diphtheria. Several had a purulent discharge from the nose without further symptoms. It may be, therefore, that gravis strains are of variable pathogenicity, but we think it more likely that there is a difference in reactivity between infants and older children.

SUMMARY

The diphtheria case fatality rate during the wartime epidemic in the Netherlands was relatively low, especially when the epidemic was at its peak.

The age distribution of morbidity showed a shift to older age groups, which may be explained to a large extent by a rapid spread of diphtheria bacilli among children, which caused early and high morbidity and spontaneous immunization rates, in contrast to the adults, among whom contact and immunization with diphtheria bacilli were much less and among whom the epidemic therefore lasted longer.

The Schick tests performed on large groups of the population in different years support this view.

III. Infection Rate; Immunization

It was not possible to determine exactly the prevalence of diphtheria bacilli among the healthy population at regular intervals. From 1930 to 1935, between 200 and 800 children, not known to be diphtheria contacts, were

examined annually and showed gradually declining percentages of positives: from 11.4 to 3 per cent. In 1940 we examined 1,119 children of the poorer classes and found only 5 (0.5 per cent) avirulent mitis strains. Thus, immediately before the outbreak of 1941 the percentage of carriers among those children was negligible.

With regard to Schick rates, there were definite differences between children in various economic groups in 1942–1943. Of 347 children of well-to-do families, between 6 and 14 years of age, 11.3 per cent had a negative Schick reaction. Of 794 children of poorer families of the same age, 33 per cent were negative; a difference of 21.7 + 2.4 per cent. Of 255 children 12–14 years of age, from middle class parents, 17.3 per cent were negative; while 40 per cent of 293 children of poor families were negative; a difference of 22.7 + 3.7 per cent. These figures indicate a relationship between Schick status of children and economic status of their parents. This may in turn be directly related to another factor which influences the spread of diphtheria bacilli and thereby the Schick reaction: namely, the number of children in a family who attend a school. There were no significant differences between the groups with two, three, or more children at school. We therefore compared only those families having one child at school (A), with those having more than one child attending school (B) (Table 8-A and B).

In 1946 at the end of the school season there was no longer any difference between groups A and B even in the youngest children (Table 8).

A great difficulty in measuring the rate and extent of spread of diphtheria bacilli by means of Schick test data is lack of knowledge of the frequency of reversion of a negative Schick reaction to a positive. We know that it does happen, but not how often. We saw, for example, that of 105 recovered diphtheria patients, at least 23 later had a positive Schick reaction. It is of interest that in 1942 the curve indicating conversion of positive to negative Schick reactions in school children remained flat after the first rise in the group which enters school. This can only be accounted for by a rather frequent reversion of Schick-negative reaction to positive in spite of the fact that the prevalence of diphtheria bacilli

TABLE 8-A

Percentage of Schick-negative Children in Families with One (A) and with More Children (B) Attending School (1942 at Beginning of the School Year)

Group	Age	Children Tested	Per cent Schick-Neg.	Age	Children Tested	Per cent Schick-Neg.	Age	Children Tested	Per cent Schick-Neg.
A	4	178	7.3	5	167	10.2	4 + 5	345	9
B	4	262	14.1*	5	301	14.3	4 + 5	563	14.2†

* Difference 7.2 ± 2.9%. † Difference 5.2 ± 2.1%.
These figures point to a great influence of the school on the spread of diphtheria bacilli.

TABLE 8-B

Percentage of Schick-negative School Children in Groups A and B in 1946 at the End of the School Year

Group	Age	Immunized Children Tested	Schick-Neg. Per cent	Non-immunized Children Tested	Schick-Neg. Per cent	Age	Immunized Children Tested	Schick-Neg. Per cent	Non-immunized Children Tested	Schick-Neg. Per cent

B	4	329	85	305	48	5	414	81	394	56

must have been highest in this age group.

IMMUNIZATION

Immunization against diphtheria has never been compulsory in Amsterdam but it was practised on a fairly large scale by the Municipal Health Service and also by private practitioners; the last in unknown numbers. The population of Amsterdam during the last decade has approximated 800,000, with about 12,000 births annually. From 1930 to 1934 a yearly average of 5,000 children were immunized by the Public Health Service with three injections of toxoid (16 L_f). From 1936 on a stronger toxoid (20 L_f) was used in only two doses of 1 and 1.5 ml. Before the war a yearly average was reached of 5,600 immunizations; from 1940 to 1943, an average of more than 16,000 were immunized annually, with a minimum of 2,700 in 1940 and a maximum of 38,000 in 1943.

In the second half of 1944 and in 1945 all immunizations had to be suspended because of the famine and other difficulties. In 1946 and 1947, immunizations again amounted to 10,000 and 47,500, respectively. However, a certain percentage of these were revaccinations (in 1943 nearly 30 per cent, in 1946 nearly 50 per cent). The results of these campaigns are reflected in the data of the school physician (Dr. Dallmeyer). In 1942–1944, when entering the kindergarten, 34, 58, and 55 per cent, respectively, of the children had been previously immunized against diphtheria. For the primary school these figures were 42, 48, and 53 per cent, respectively. So immunization was not neglected as G. W. Anderson suggested.[7]

The effect of these immunizations upon the course of the epidemic is difficult to determine. It cannot be measured by the data on morbidity in the various age groups (Figure I), which can be accounted for quite well by the difference in spread of diphtheria bacilli in these groups. Since immunizations were performed only on a voluntary basis there was necessarily a certain selection of the immunized, and therefore comparisons lose much of their significance. We have tried to obtain a more reliable measure of the effect of immunization by comparing the number of immunized among the patients and among the healthy contacts of the same families. In these two groups circumstances are comparable (Table 9).

In the older age groups there is practically no difference. We are aware of the fact that in a number of families the importation of the disease may have been prevented by the immunization but we think this does not alter the value of the figures in Table 9.

A curious fact is that when the different types of diphtheria bacilli were taken into consideration there was no difference either. In 1942, of all members of the families in which a gravis case had been diagnosed, 29.4 per cent had been previously immunized; of the gravis patients themselves 28.4 per cent. For the intermedius type these figures were 31.8 per cent and 27.6 per cent,

TABLE 9

Percentages of Immunized Children among Diphtheria Patients and Their Contacts in the Same Families in 1942

	3–5 Years		6–9 Years		10–14 Years	
Children	*Number*	*Per cent Immunized* *	*Number*	*Per cent Immunized*	*Number*	*Per cent Immunized*
Patients	175	15.3	239	27.8	298	28.6
Contacts	190	21.9	305	30.9	510	29

* Among the 3–5 years group there is some difference (6.6 ± 4%) but this is not significant.

respectively; for mitis infections, 23.6 and 23.4 per cent.

The results obtained with the Schick test also gave the impression that the immunizations had not been very satisfactory. For example, in 1942 the immunized group showed only about 50 per cent Schick-negatives (Figure II). Before 1942 the prevalence of diphtheria bacilli among the population must have been extremely low. Evidently spontaneous immunization by means of contact with normally circulating diphtheria bacilli was rare. In the artificially immunized children the stimulus of the toxoid must have been too small to keep the level of antitoxic resistance high, especially in those to whom only two injections of toxoid had been given. In a comparative study in 1942, a rapid decline was seen in the percentage of Schick-negatives one year after immunizations, except among those to whom three injections of toxoid had been given in combination with scarlatina toxin. In these groups after 2 years 92 per cent were still Schick-negative. In those children who had received only two injections of the strong diphtheria toxoid, no more than 41 per cent reacted negatively after 2 years. In previous experiments these vaccines had all been checked by means of the Schick reaction 3 months after immunization and had given good results. It seems, therefore, that a spontaneous reversion of Schick-negative to positive must have been fairly rapid and frequent.

The considerations related above all point to the fact that in the great wartime epidemic of diphtheria in Amsterdam, immunization on a fairly large scale could not prevent the outbreak nor alter its course to a large extent. We think that a better antigen, given in more than two injections, in the whole younger population, might have produced better results, and should be advocated for the future. This is in agreement with Frobisher.[8]

SUMMARY

1. Before the wartime epidemic very few diphtheria bacilli were circulating among the population.

2. During the epidemic the circulation must have been extremely high among children and less among adults which is reflected in the Schick and morbidity curves.

3. When the epidemic began to subside it did not diminish immediately.

4. The school was the place where most infection occurred.

5. The Schick status of children was correlated with the economic status of the parents.

6. Immunization against diphtheria was practised on a fairly large scale but it seems to have had little influence on the course of the epidemic.

Observations on the Epidemiology of Shigellosis among Institutional Inmates in Puerto Rico*

GUILLERMO ARBONA, M.D., M.P.H., F.A.P.H.A., AND LUIS GONZÁLEZ, PH.D.

Head, Department of Hygiene, and Assistant Professor of Bacteriology, School of Tropical Medicine, San Juan, P. R.

BACILLARY dysentery is known to be highly endemic in tropical and subtropical areas. According to Costa Mandry,[1] many references to epidemics of diarrheal disorders are found among the reports of early historians of Puerto Rico. In 1902, Flexner recovered the dysentery bacillus from a soldier who had been stationed on the Island and had presumably acquired the infection at the time. Some years after, González Martínez and Costa Mandry[2] studied several diarrheal outbreaks which proved to be of bacillary origin. In 1941, Watt, Hardy, and DeCapito[3] reported an infection rate of 4 per cent among normal population groups and one of 10 per cent among inmates of the Puerto Rico Psychiatric Hospital.

The present study was conducted in two of the wards of the Puerto Rico Psychiatric Hospital from January, 1946, to January, 1947. The first ward is one where all male admissions to the institution are kept for periods of observation ranging from 1 to 6 weeks. In addition, the ward is used as a sort of infirmary for inmates suffering from concurrent acute diseases. It has a capacity of 75 beds. During the period of study 527 inmates were observed indicating a large turnover of patients.

The other ward, with a capacity of 100 beds, is used for the care of women inmates, mostly inmates who have been confined in the institution for a long time. During the course of this survey, a total of 219 female inmates were studied.

Sanitary conditions are very poor in both wards. Most of the inmates eat their meals either sitting on their bed or on the floor. Many of them defecate on the floor, especially in the evenings. Surprisingly enough, very few flies are seen, yet conditions in general are ideal for person to person transmission and transmission through the contamination of foods.

At weekly intervals, fecal specimens were obtained from inmates in both wards by the rectal swab method described by Hardy, *et al.*[4] These specimens were immediately planted on S.S. agar plates and incubated for 24 hours at 37° C. Suspicious colonies were then transplanted to Krumwiede's triple sugar slants and, after incubation for 24 hours at 37° C., suspicious growths were transplanted to extract broth for later planting into carbohydrate-containing media for study of fermentation and indole reactions. Cultures were finally typed, using the precipitin test described by González and Morales Otero.[5]

* Read before the Epidemiology Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

TABLE 1

Shigellosis Study — January, 1946, to January, 1947
Puerto Rico Psychiatric Hospital
Results of Examination of Inmates

		Inmates Examined	Observed Infected		Specimens Examined	Positive		Specimens per Inmate
			Number	Percentage		Number	Percentage	
Men's Ward	Inmates admitted before Nov. 1945	304	44	14.5	1,912	58	3.0	6.3
	Inmates admitted after Nov. 1945	223	40	17.9	981	63	6.4	4.4
	All inmates	527	84	15.9	2,893	121	4.2	5.5
Women's Ward	Inmates admitted before Nov. 1945	192	53	27.6	3,531	91	2.6	18.4
	Inmates admitted after Nov. 1945	27	9	33.3	168	18	10.7	6.2
	All inmates	219	62	28.3	3,699	109	2.9	16.9
Both Wards	Inmates admitted before Nov. 1945	496	97	19.6	5,443	149	2.7	13.7
	Inmates admitted after Nov. 1945	250	49	19.6	1,149	81	7.0	4.6
	All inmates	746	146	19.6	6,592	230	3.5	10.2

PREVALENCE OF INFECTION

A total of 6,592 fecal specimens from 746 inmates was collected and examined and 230, or 3.5 per cent, were found positive (Table 1). Of the specimens obtained from the male inmates, 4.2 per cent were positive as compared to 2.9 per cent of those obtained from female inmates.

So as to compare the prevalence of infection among inmates who had been in the institution for a long time with that among inmates who had been recently admitted, the 746 inmates of both wards were divided into two groups; one composed of those admitted before November, 1945, and the other of those inmates admitted after November, 1945. Of the specimens obtained from the second group, 7.0 per cent were positive as compared to only 2.7 per cent in the first group. The higher percentage of positive samples found among the men may be explained by the fact that among them the proportion of inmates admitted after November, 1945, was larger.

Of the total of 746 inmates examined, 146, or 19.6 per cent, were found infected at one time or another: 84 of the 527 men and 62 of the 219 women (15.9 per cent and 28.3 per cent, respectively). It must be borne in mind, however, that female inmates were observed, on the average, for a period three times as long as the male inmates and that 16.9 specimens were examined per each female inmate, as compared to only 5.5 samples per each male. The proportion of inmates admitted before November, 1945, that were infected was 19.6 per cent, the same as for inmates admitted after November, 1945. Again it must be borne in mind that the inmates admitted after November, 1945, were observed for about one-third of the time that obtained for those admitted before November, 1945.

TYPES OF ORGANISMS ISOLATED

The different types of organisms isolated are tabulated in Table 2; 52.8 per cent belonged to the Flexner group, of which the most frequently found were types IV and I–III. Next in frequency of isolation was *Shigella schmitzi* (32.5 per cent), followed by *Shigella alkalescens* with 14.7 per cent. *Shigella*

TABLE 2

shiga and *S. sonne* were never isolated. *S. shiga* has never been reported from Puerto Rico, though *S. sonne* has. In a previous survey,[6] conducted by the writers in this same institution, one of the most prevalent Flexner types of *Shigella* was type VI, or Newcastle. During the present study this organism was isolated on one occasion only.

DURATION OF INFECTION

The number of consecutive weeks during which the various organisms were isolated was recorded. In estimating the average duration of infection from these data, it is assumed that, on the basis of one isolation, infection could have lasted from 1 to 13 days; that when the organism was isolated twice consecutively, the period of infection could have been anywhere from 8 to 20 days, and so on. Duration of infection was thus estimated at from 8 to 23 days for all inmates, 6 to 21 days for inmates admitted before November, 1945, and 12 to 30 days for inmates admitted after November, 1945.

A small number of admissions were followed up from day to day to determine the duration of infection more exactly. Of 75 such admissions, 16 were infected and the average duration of the infection was 15 days. In the entire study the infection of shortest duration was of 1 day and the longest of 51 weeks.

TIME OF INFECTION

Of the 746 inmates studied, 42, or 5.6 per cent, were found positive on the first sample examined. Of the 704 inmates found negative on the first examination only 507 were examined again, and of these, 47, or 9.3 per cent, were found positive on the second to fifth examination. Only 282 of the 460 that were still negative were examined further and 24, or 8.5 per cent, were found positive on the sixth to tenth specimen. On the 11th to 20th additional specimen taken from 172 of the inmates who had remained negative, 11, or 6.4 per cent, were positive.

Inmates admitted after November, 1945, were observed to become infected earlier than those admitted prior to November, 1945. There was not much difference between the two groups in the proportion of infections on the first examination: 6.0 per cent in the former group as compared to 5.6 per cent in the latter. On the second through fifth specimens, however, 13.1 per cent of the newly arrived were observed infected in comparison to only 7.5 per cent of those admitted before November, 1945.

SEASONAL VARIATION

In January, 1946, the percentage of positive samples from inmates in both wards was 6.4, it went down to 3.8 in February and 1.8 in March, staying at a low level through June. In July this rate went up to 4.4, staying at a higher level through December, going down to 2.6 in January, 1947 (Figure 1).

The infection rates for inmates admitted before and after November, 1945, show similar trends, the infection rates for the inmates admitted after November, 1945, being much higher

and the peaks steeper, however. It should be noticed that the rise in July is much slower among the female inmates, rising from 1.2 per cent in June to 1.7 per cent in July to 2.6 per cent in August, reaching a peak of 6.6 per cent in September, while among the male inmates the rate rose from 2.1 per cent in June to a peak of 7.7 per cent in July (Figure 2).

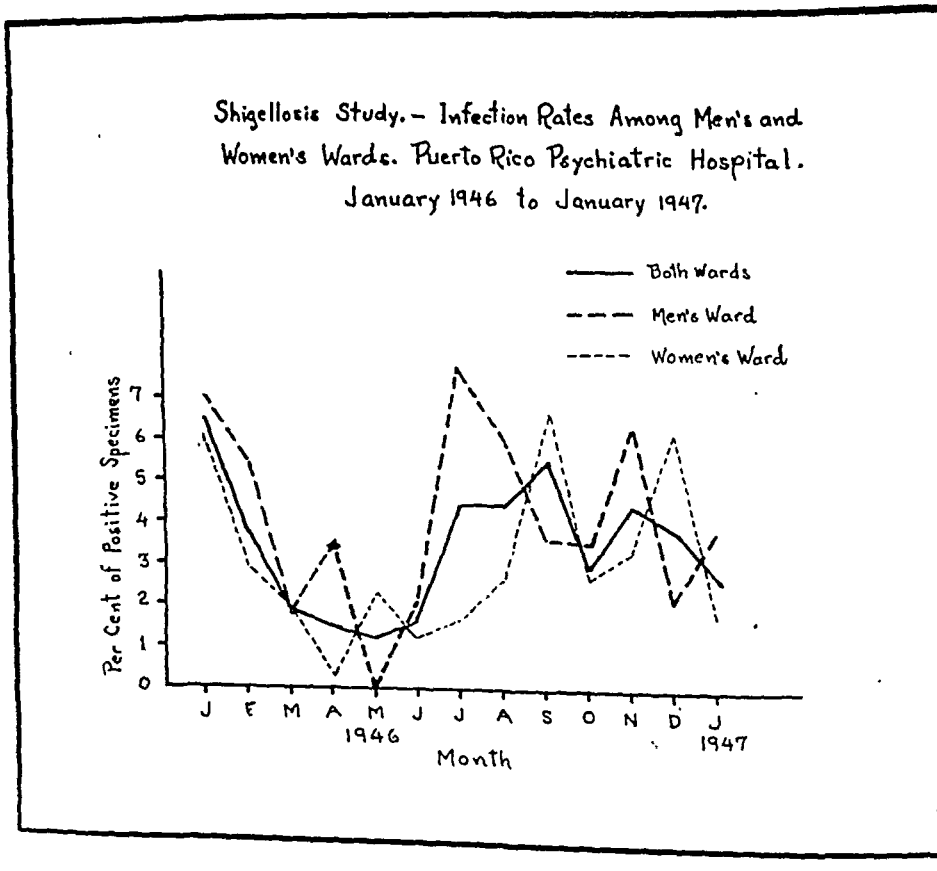
INFLUENCE OF ADMISSIONS ON PREVALENCE OF INFECTION

It has been pointed out that the infection rates among recently admitted inmates were higher, especially during their first weeks of stay in the wards, and that infections among these inmates lasted for a longer period of time. From these observations, it could be expected that an increase or a decrease in the number of new inmates admitted would influence the prevalence of infection in the ward. In Figure 1, in addition to the infection rates per month, the admissions during each month have been plotted. A suggestive similarity in the contours of the curves representing the infection rates and the number of admissions is observed; the peaks and dips in the curves representing the admissions usually precede those in the curve representing the infection rates both for inmates admitted before and after November, 1945.

REINFECTION

In a previous study conducted with these same patients[7] and during the present one, 162 inmates were followed

FIGURE 1



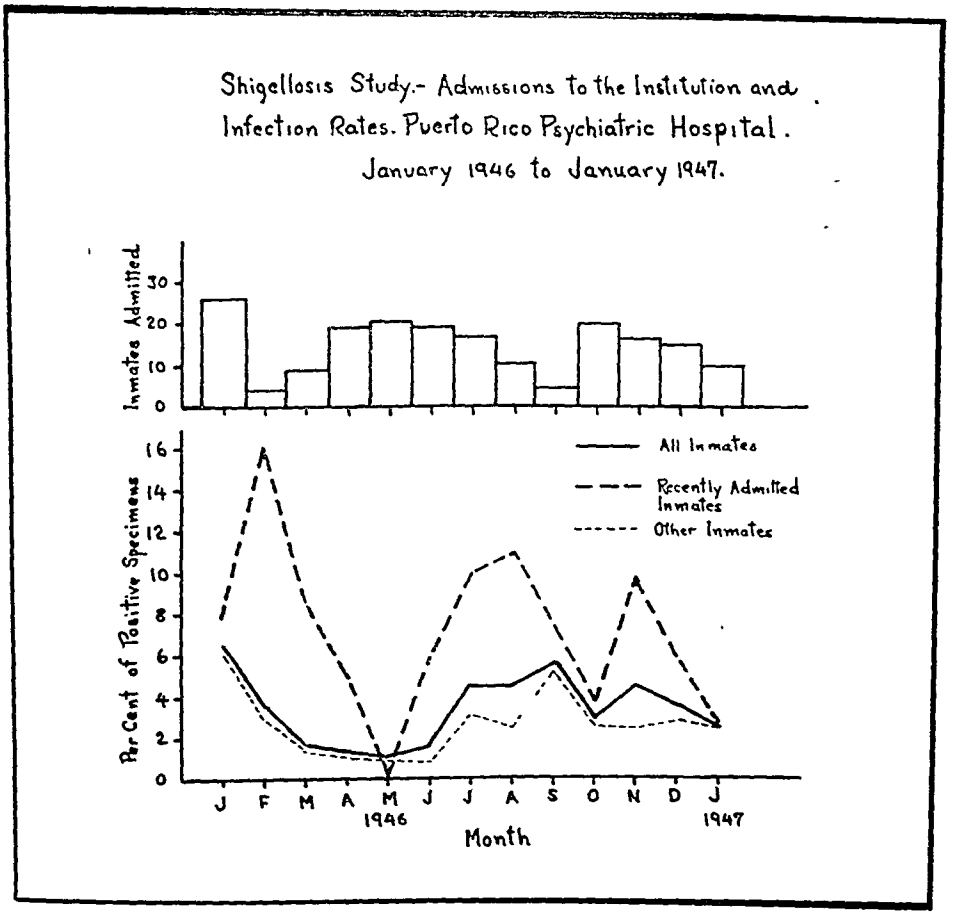


FIGURE 2

up for more than 4 weeks after their first infection and in 45, or 27.8 per cent, reinfections were observed. A reinfection was recognized if a patient who had been negative for 4 or more consecutive weeks after the first infection, became infected again with a different *Shigella* organism; or negative for 12 or more consecutive weeks and again infected with the same type of *Shigella* organism. In Table 3 the individuals classified, according to the type of organisms responsible for the first infection, and showing the organisms found in the reinfection are presented.

Patients originally infected with Flexner type IV organisms were found less frequently reinfected; in fact, in 23 patients studied, only one reinfection was noted. If reinfection rates are an index of the immunity produced by infection with these organisms, it can be said that Flexner type IV organisms seem to confer a longer lasting immunity against the different types of *Shigella* organisms isolated in the present study. Such a finding may be explained, in part, by an observation of González,[8] who found that old cultures of Flexner type IV organisms are agglutinated by antisera prepared against practically all members of the Flexner group.

CLINICAL OBSERVATIONS

Owing to the lack of personnel and to the poor coöperation that can be ex-

pected from psychiatric patients, no detailed clinical observations were made. It is the general impression of the writers, however, that acute clinical attacks of the classical type of dysentery were few, if not rare. Benign diarrheal attacks, associated with infection with *Shigella* organisms were frequent, but the majority of infected inmates followed up did not show any symptoms whatsoever.

SUMMARY AND CONCLUSIONS

1. A study on the prevalence of *Shigella* infections in inmates of two wards of the Puerto Rico Psychiatric Hospital was carried out over a period of 13 months—from January, 1946, to January, 1947.

2. Of 6,592 fecal samples examined, 230, or 3.5 per cent, were positive for *Shigella* organisms. These specimens were obtained from 746 inmates, of which 146, or 19.6 per cent, were found infected. The average number of specimens examined per inmate was 10.2.

3. Infection rates were much higher (7.0 per cent) among recently admitted inmates than among those in the institution for long periods of time (2.7 per cent). These rates were higher among men (4.2 per cent) than among women (2.9 per cent).

4. The organisms isolated belonged to the Flexner, *schmitzi,* and *alkalescens* groups of *Shigella;* the types of organisms isolated tended to be different at different times of the study. No shiga or Sonne organisms were isolated, though the latter has often been reported in Puerto Rico.

5. The average duration of infection was estimated at approximately 1 to 4 weeks; duration of the infection was longer in inmates recently admitted to the institution.

6. While 19.1 per cent of the recently admitted inmates were observed infected during their first 5 weeks of observation, only 13.0 per cent of the other inmates were found to be infected during the first 5 weeks that they were studied.

7. Infection rates were lower during the first half of the year, January through June, the cooler months of the year in Puerto Rico, and higher during the latter half, July through December, the warmer months.

8. Infection rates appeared to be influenced somewhat by the number of admissions to the institution, rising soon after a large number of admissions and decreasing when the number of admissions decreased.

9. Of 162 inmates who were infected and followed up for 4 or more weeks after they had lost their infection, 27.8 per cent were reinfected. Those originally infected with the Flexner type IV organism showed less reinfections.

10. It appears from these observations that inmates entering the Puerto Rico Psychiatric Hospital from among the general population, where the prevalence of shigellosis is lower, have less resistance to infection with these organisms than inmates who have been in the institution for long periods of time. This lesser resistance is manifested by higher infection rates after they are admitted to the institution and by a longer duration of infection.

11. Although meager clinical observations were made, it is the impression of the writers that infection with *Shigella* organisms was accompanied by very mild if any symptoms. It was our impression that for the most part infected inmates were in a carrier state.

12. It is evident from this study that infection with *Shigella* organisms does not protect for long against subsequent infections. It may be that frequent infections protect against clinical attacks of classical bacillary dysentery.

NOTE: We are indebted to the members of the Staff of the Puerto Rico Psychiatric Hospital for the fine coöperation and assistance given us at all times.

Educational Qualifications of Community Health Educators

"HEALTH EDUCATORS: High standards for professional health educators are set forth in the latest report of the Committee on Professional Education (American Public Health Association). The report, approved by the A.P.H.A. Governing Council in November, outlines seven major areas of knowledge and competence as desirable in health educational personnel.

"They are: (1) *Basic Cultural Education*—use of the English language, general psychology. U. S. and world history; (2) *Basic Sciences*—some knowledge of chemistry, bacteriology, physiology, physics and biology; (3) *Education and Educational Psychology;* (4) *Social Sciences*—background in general sociology, political economy and cultural anthropology; (5) *Public Health Training*—knowledge of principles of organization and administration of public health, methods of communicable disease control, public health statistics; (6) *Public Administration*—training in community organization, background in social work agencies; (7) *Special Skills in Health Education*—public speaking, writing and edition; all other skills associated with publicity work."

Channels, Vol. 1. No. 8 (Dec. 15), 1948.

Arctic Sanitation*

W. A. HARDENBERGH, F.A.P.H.A.

Editor, Public Works Magazine, New York, N. Y.

STRICTLY speaking, the Arctic comprises that northern section of the world where the ground is permanently frozen, even though the top layer of soil may thaw during a brief summer period. The southern limit of this permanently frozen ground, which is called permafrost, coincides generally with the northern limit of tree growth—the tree line. However, for the purposes of this paper, the Arctic will be considered as the entire northern area where extreme cold persists throughout a major portion of the year.

Occasional low temperatures alone do not indicate arctic conditions. Records show that as low temperatures have occurred in the continental United States as in the extreme polar regions; but such low temperatures do not persist outside of the Arctic. Wind; lack of forest growth; continued very low temperatures; a short summer; and permanently frozen ground are characteristic of the Arctic.

The general problems of cold weather sanitation are not insurmountable in themselves, but the difficulties that exist are heightened by the combination of the military problems and those resulting from the hostility of the climate; the inefficiency of men working in extreme cold; the difficulty of merely sustaining life; the great distances; and the necessity for shelter. In a broad way, we may say that the problems of the Arctic are much the reverse of those we faced in the tropics. There we could not completely protect the health of small groups; in the Arctic, the difficult problem will be the supply and protection of large groups. Fortunately, there are no rats and no cockroaches in the Arctic, though there are mosquitoes and many varieties of gnats and biting insects.

Local food supplies for large bodies of men are, to all intents and purposes, nonexistent. Shelter is also practically nonexistent, and in time of storm is essential. Snow houses, or igloos, can be constructed for small groups, but not readily for an army. Travel and transportation over land are possible in the winter but not in the summer. Snowshoes or skis are necessary for winter travel by individuals. Tracked or crawler vehicles are the only kind that can move off the probably ten miles of hard surfaced roads in the far north. Sleds can be hauled by these vehicles along previously selected trails only during the winter. Fuel, food, and shelter must be taken along; they do not exist in the Arctic.

WATER SUPPLY

For 7 or 8 months each year, all lakes and rivers are covered with 6 ft. or more of ice. Small streams are frozen solid. Since the ground also is frozen, there are many problems of water supply.

Fixed supplies must be drawn from under the ice cover. This means that the pond or reservoir or other source must be of sufficient capacity to supply all needs for about 8 months, assuming (1) that the top 6 or 8 ft. will freeze,

* Presented at a Joint Session of the Inter-American Association of Sanitary Engineering and the Engineering Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

and (2) that there will be no winter inflow. Since many of the smaller arctic lakes and ponds are relatively shallow, the contours between which the water supply can be drawn may need to be determined accurately.

The amount of water required by fixed posts has not been determined. Estimates of needs range from 5 to 70 g.p.c.d. The former is no doubt inadequate for any normal conditions; design should probably aim at the latter. Water is generally quite plentiful in the Arctic. Though the rainfall is small, it cannot soak into the permanently frozen ground and so stands in pools or runs off.

Water supplies will usually come from surface sources. As yet we do not know enough about arctic ground waters to make definite statements regarding them; but there have been difficulties in sinking and maintaining wells through permafrost and in finding adequate supplies of good quality ground water.

The quality of arctic ground waters appears to be good. It is generally clear and without objectionable characteristics. We need to know more about its chlorine demand and other factors in treatment.

Pumping stations must be designed and constructed with due regard to permafrost conditions. Steam-operated pumps may be desirable as power must be generated locally with fuel, and the steam can be used to heat the water. As drawn from lakes in the winter, water temperature is about 33° F. It is normal practice to raise the temperature to 40° to 75° F. at the pump.

Distribution and storage offer many problems. Storage tanks are frequently housed to protect them from the cold. The force line from the pumping station to the storage reservoir must be insulated. Circulation is usually provided by a small bleed-off main which takes water from the storage tank and returns it to the pump sump. Fully satisfactory protective methods to prevent pipe lines from freezing have not been developed. The "utilidor" system, in which the water, sewer, and steam lines are carried in a single concrete box, is costly and has sanitary objections. Service connections also need protection. It must be remembered that all of these lines must be located in ground that is solidly frozen during much or even all of the year.

In the field, in the winter, water must be procured by melting snow or ice, preferably the latter, since much more water is obtained and more easily. To supply the necessary amount of water, melting devices and fuel must be provided; and to transport the water, insulated containers are necessary. Equipment to meet the needs of arctic field water supply is being developed and tested but, as yet, there are no standard methods or devices applicable to large scale, universal field use. Insulated water carts, simple snow melting devices, and perhaps insulated canteens may be needed.

SEWAGE AND WASTE

The need for adequate waste disposal, or even of any method of disposal in the field, aside from tossing the wastes off the trail has been questioned. This viewpoint seems wholly erroneous. It is true that the Arctic is a vast region; however there is no assurance that each and every group or party will follow a different route. In fact, the exact opposite is most likely. If the idea gets into the minds of our line officers that sanitation is unnecessary in cold areas, it will take both epidemics and time and trouble to change some of them; the rest will never change. We cannot foresee what our needs or our activities will be in the Arctic, so we should not abandon time-tested practices in sanitation, certainly not until we know more of the situation.

In fixed posts, water-carried sewage disposal is desirable, though indoor chemical toilets have been used with some degree of satisfaction. Sewers are subject to the same problem of freezing as are water mains. They should probably be insulated and a small steam line laid alongside or under the pipe. Treatment plants will probably not be needed, since main posts will probably be on deep water and disposal by dilution can be employed. If treatment should be necessary, heat will probably have to be provided and the plant structures must be carefully designed for permafrost conditions.

Field disposal of sewage is an unsolved problem as yet. Pits are difficult or impossible to dig in frozen ground. Chemical toilets of the pail type seem promising. Disposable linings for these toilets are being tried, but getting rid of the lining and contents is a problem. Perhaps a chemical can be developed which, when the contents thaw in the summer, will provide effective sterilization. Mere tossing aside of these used containers, especially when the number of men involved is considerable, is certainly open to serious question. Protecting the men from the weather while using toilet facilities is necessary, and as yet no standard practice has been developed.

INSECT CONTROL

There are many mosquitoes during the short arctic summer; also various flies and other biting insects. Mosquito breeding starts as soon as the snow begins to melt, since the eggs are laid the previous fall. While there are probably no mosquito-borne diseases in the Arctic, the problem of comfort is an important one. Area control with DDT and other compounds has been tried. In general, because insects from outside the sprayed area move in very quickly, relief is of short duration, even when a considerable area is treated. Work has been done on the application of insecticides to the snow before melting begins, and results have been promising.

FOOD, SHELTER, TRANSPORTATION, AND CLOTHING

In field service, away from fixed posts, consideration must be given to such other factors as food, shelter, transportation, and clothing. Developments in shelter and transportation may influence, to a marked extent, the details of sanitation practices. If, for instance, overland transportation is developed beyond present ideas, sanitation problems might not be too different from those that we now have in the northern part of this country. We would have weather that averages colder and stays colder longer, but there would probably not be as much snow to contend with. Distances would be greater, especially distances from our main supply bases. Forest cover, and with it local fuel and shelter resources, would be lacking. Summer travel over land would be impossible and summers would be much shorter. But with all of these differences, our own north country would form a good basis from which to start considerations of the problems of arctic sanitation.

Nutritional Reconditioning of Children*

ELSIE Z. MOYER AND ICIE G. MACY, PH.D., F.A.P.H.A.

Research Laboratory Staff, Children's Fund of Michigan, Detroit, Mich.

TO extend knowledge of the nutritional status of Michigan children, the Research Laboratory of the Children's Fund of Michigan studied 392 boys and girls, from 3 to 18 years old, while they were being supervised by five widely separated rural and urban child caring agencies in the state.[1-8] The investigation was made possible by the development of accurate microtechniques—methods using small samples—for chemical analyses of blood. These procedures make practical studies of groups of individuals while they are living in their usual environments. The ease with which the small blood samples are collected, with minimal requirements for equipment and personnel at point of collection and the relative simplicity of shipping samples to a central laboratory for analysis make the procedures specially suitable to obtaining information of value in the public health field.

Finger punctures provided fasting blood samples approximately 0.3 ml. in volume, an amount adequate for determination of hemoglobin, serum protein, serum alkaline phosphatase, vitamin A, carotene, and vitamin C by the Lowry and Bessey micromethods.[2] The results of the studies of children attending Bay Cliff Health Camp located on the shore of Lake Superior in the Upper Peninsula of Michigan demonstrate the possibilities of nutritional reconditioning.

During six weeks each summer the Bay Cliff Health Camp provides for underprivileged children diets superior in quantity and quality, excellent environment, and activities planned for their enjoyment by an experienced staff. The children in the camp had: (1) cardiac involvement, (2) speech and hearing defects; (3) orthopedic ailments principally residual from poliomyelitis, but including a few cases of spasticity and other debilitating conditions; and (4) general malnutrition or undernutrition common to underprivileged children. Many of the children were known to have existed for years in an environment that did not provide even the minimal amounts of nutriments necessary for satisfactory nutritional status. With some, chronic misfeeding and underfeeding dated from birth, and their bodies may have become conditioned to inadequate diets. Others had deficiencies secondary to physical and emotional handicaps which possibly interfered with the ingestion, absorption, or utilization of essential nutriments.

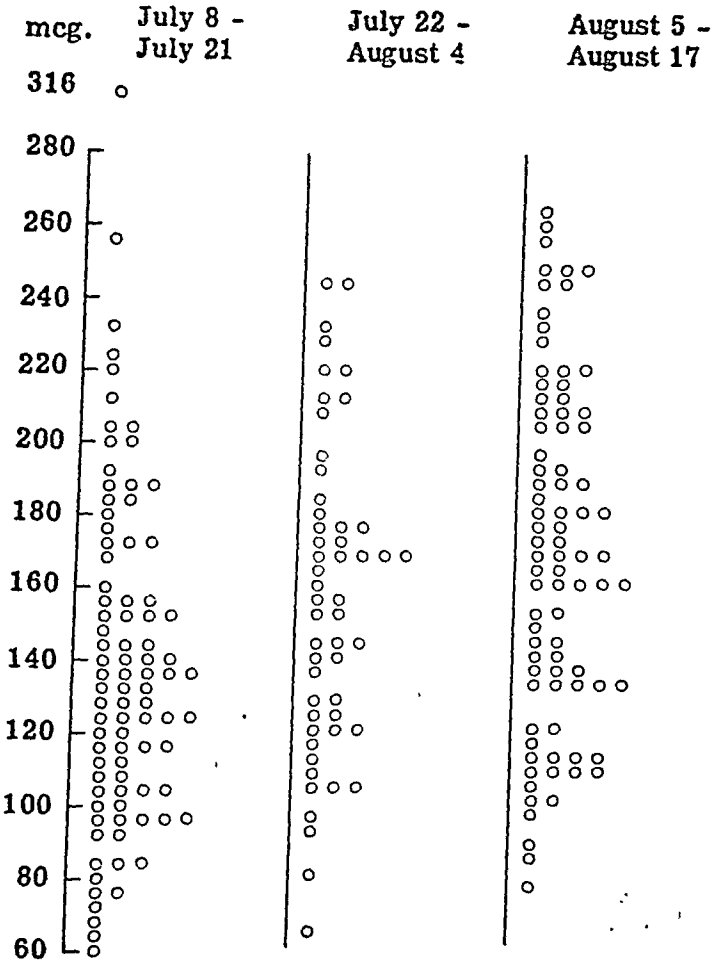
Weight gain is often taken as the criterion of satisfactory growth in children. Of the 101 children studied at Bay Cliff Health Camp 73 had not attained the weights expected for their respective ages, according to the standards of Meredith[9] and Boynton,[10] when they were admitted to camp. Of these, 53 weighed 80–100 per cent of their standards, 15 weighed 70–80 per cent of their standards, and 5 weighed less than 70 per cent of the normal expectation. During the camp period average body weight gains ranged from 5 to

* Presented at a Joint Session of the American School Health Association and the Food and Nutrition Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

1,191 gm. per week. For the majority of the children in the group weight gain alone would be indicative of the beneficial effects of the camp experience. However, chemical methods make possible more objective determinations of physiological status, coincident with clinical examinations and evaluation of the results of a changed environment.

Serum alkaline phosphatase—Since interest developed in serum alkaline phosphatase as an indicator of rickets, it has continually become more evident that many factors are operative in determining the level of the enzyme in blood serum. Also, serum alkaline phosphatase values can be interpreted only with recognition of the numerous physiological processes which influence its concentration in the blood stream. In recent surveys of the nutritional status of population groups,[11, 12] the measurement has been employed, primarily, for detection of vitamin D deficiency.

The children at Bay Cliff Health Camp did not show any changes in serum alkaline phosphatase levels during the six weeks of improved environmental and dietary regimen, nor was there any indication that any of the levels were abnormal when age and sex were considered.[8]



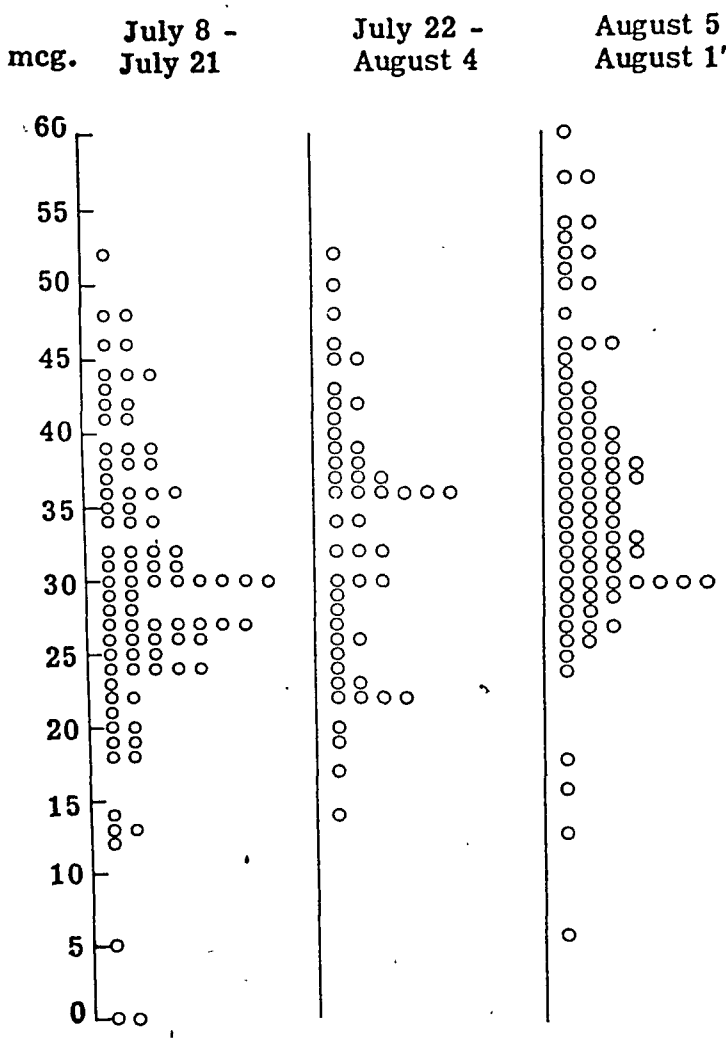
Serum vitamin A and carotenoids—An interpretation of data on serum concentrations of vitamin A and carotenoids as they relate to nutritional status is complicated. It is known that blood carotenoids drop rapidly over a period of one week when a carotene-free and vitamin A-free diet is given,[13–15] but many months of a deficient diet are required to depress appreciably the serum vitamin A level. Malnourishment is frequently associated with low serum vitamin A levels,[16, 17] and Yarbrough and Dann[18] have demonstrated lower average vitamin A levels in the blood of low income groups than among high income groups. On the other hand, not all persons showing commonly accepted clinical signs of vitamin A deficiency exhibit lowered blood levels of this substance, and dark adaptation measurements may show poor correlation to blood levels of vitamin A.[19, 20]

The vitamin A problem is complicated by the fact that certain carotenoid pigments in food are converted to vitamin A in the body and serve as sources of additional amounts of this indispensable material. The human body has the capacity of storing vitamin A, particularly in the liver. For this reason, restricted intake of vitamin A will not produce vitamin A deficiency as rapidly as ascorbic acid limitation will cause scurvy, and blood levels of vitamin A will not respond as rapidly to lowered dietary intake of the vitamin as do the blood levels of vitamin C when intake is restricted.

Dietary supplies of vitamin A may vary significantly with season. Butter —one of the few rich natural sources of preformed vitamin A in a diet—has been shown[21] to have significantly lower vitamin A potency in the winter months when green pasturage is not available. More important than vitamin A itself in satisfying needs for this nutriment are the carotenoid pigments of green and yellow vegetables and fruits. Moore[22] has pointed out that these, being the less expensive sources of vitamin A, are the most significant ones in the diet. It is difficult to assess the vitamin A value which the mixed carotenes of any diet may contribute. Of the several carotenes, some are well and extensively converted into vitamin A when they enter the body; others are but poorly converted, if at all.[23] Recently, Koehn[24] obtained results with rats which support the theory of Karrer that the conversion of beta-carotene to vitamin A, *in vivo,* is by fission of the molecule to yield two molecules of vitamin A.

The blood serum levels of carotenoids for the children at Bay Cliff Health

FIGURE 1



Fasting serum carotenoids levels of children at Bay Cliff Health Camp

Camp are shown in Figure 1. The values are distributed among three intervals: those from blood collected during the first and second weeks of camp, those collected during the third and fourth weeks, and those after the children had been in camp for four weeks.

That blood serum levels of carotenoids may rise fairly rapidly under favorable circumstances is demonstrated by the marked increases shown by the children during the six weeks in which their environment and diet were excellent and included plentiful amounts of milk, fruit, and fresh green and yellow vegetables. The average level of serum carotenoids early in the camp period was 137 μg., and at the end, 168 μg. per 100 ml. Initially, only 17 per cent of the group had serum carotenoid levels above 160 μg. per 100 ml., but after four to five weeks 55 per cent had risen to that level. The ample levels of serum carotenoids imply that this material was available in the diet in substantial amounts.

Values for vitamin A are plotted similarly in Figure 2. Among the children, 42 per cent had initial levels of serum vitamin A below 30 micrograms

FIGURE 2

Fasting serum vitamin A levels of children a Bay Cliff Health Camp

per 100 ml., but only 27 per cent of the final values were at or below this level. The greatest increases in blood vitamin A occurred in the children whose initial levels were lowest, while those subjects with good initial levels of vitamin A (above 30 μg.) per 100 ml. showed smaller increases and in some instances a reduction. The shift of blood vitamin A levels, while not as great, was similar to the change in carotenoid values.

Hemoglobin—Of all the biochemical measures available for assessing nutritional condition, hemoglobin concentration in the blood has been used most frequently. The occurrence of iron as a component of the hemoglobin molecule and the occurrence of iron-deficient anemias when iron and copper intakes are restricted has led to the use of hemoglobin determinations to assess adequacy of iron allowance. However, many dietary factors, such as other minerals, amino acids, and vitamins, are required simultaneously to maintain normal function of the hematopoietic

system.[7] Thus, hemoglobin concentration is a valuable indicator of adequate nutrition with respect to many, rather than to a single nutriment and is a most useful method of assessing dietary adequacy of groups, despite the fact that individual cases of anemia may often be the result of some pathological process unrelated to a deficiency in intake.

Study of healthy individuals has revealed that a wide normal range of hemoglobin levels exists and that establishing a definite level below which a value can be considered pathologic is virtually impossible.[25-29] Various standards of normalcy have been used by workers who have determined hemoglobin in assessing nutritional state. Guest's study of 600 children[30] indicates that 12.5 gm. of hemoglobin per 100 ml. of blood is a desirable level for children eighteen months old, and from all reports[31-33] it seems that for older children, values below 12.5 gm. may justifiably be considered unsatisfactory.

The distribution of the children according to level of fasting blood hemoglobin showed averages for all children ranging from 11.0 to 17.5 gm. per 100 ml., averaging 13.4 gm. A few unusually high values were found in children who had cardiac involvement. No serious degree of anemia existed in the subjects. However, 32 per cent fell below 13.0 gm. per 100 ml., and 20 per cent of the subjects had less than 12.5 gm. of hemoglobin per 100 ml. of blood. Only 3 per cent were below 12.0 gm. per 100 ml.

The distribution of values was consistent with the observations of Mugrage and Andresen,[28, 34] who found a similar range in children from birth to 21 years and of Milam and Muench[35] in studies of North Carolina populations, but in this investigation there were fewer cases of low hemoglobin than the latter workers observed. Ross and Summerfeldt[36] reported somewhat lower average values for children, in a rural orphanage (10.4 gm.), in a city institution (11.8 gm.), of middle class (12.0 gm.), and privileged children (13.0 gm.). In the absence of other evidence, the slightly reduced levels of hemoglobin existing in a few of our subjects cannot be assumed to have had their origin in dietary inadequacies. Thus, the children had representative hemoglobin levels upon entrance and did not show the effect of nutritional conditioning which was found in their levels of fasting blood serum vitamin C[4] and vitamin A.[6] Perhaps a longer exposure to improved diet would also have demonstrated a rise in hemoglobin levels.

A special study of the iron intake of two 8 and two 12 year old children demonstrated the importance of the method of determination in the evaluation of hemoglobin data. Analyses of foods exactly representing those eaten showed intakes of 15 to 21 mg. of iron per day. However, calculation with values from the literature indicated intakes of only 10 to 15 mg. per day. The fasting hemoglobin levels of the four children ranged from 12.7 to 14.8 gm. per 100 ml. of blood. This discrepancy between the calculated and analyzed values for the iron content of foods may be attributable to a location in an iron ore region. The iron content of food grown in such soil might be several times that of foods grown in another area. The absence of low hemoglobin values for the children at Bay Cliff Health Camp may well have been the result of geographic environment which assured adequate iron intakes.

Serum protein—The use of total serum protein concentration measurements in surveys of populations, with and without fractionation into component albumin and globulins, has been widespread.[12, 37-39] The majority of workers agree with the limits of normal blood serum protein concentration set by Bruckman, D'Esopo, and Peters,[40]

6.5 to 8.4 gm. per 100 ml., and that concentrations of serum protein below 6.0 gm. per 100 ml., except in infants, are indicative of pathology.

For the children who attended Bay Cliff Health Camp the means were similar for the initial and final determinations, but seven individuals showed concentrations below 6.6 gm. initially, whereas only two showed less than that concentration of serum protein near the end of the camp period.

Serum vitamin C—Serum vitamin C levels tend to reflect recent dietary intake[41–43]; therefore, by taking samples following night fasts of 12 hours or more, effects of recent intakes of vitamin C-rich foods are minimized, and the levels observed become a more valid representation of nutritional condition. Although doubt may exist when the vitamin C content of a single blood sample is taken as the criterion of vitamin C saturation in an individual, the overall picture obtained in a survey is of greater reliability in revealing the nutritional status of a large group.

In using blood levels of vitamins as indices of nutritional status, the greatest difficulties lie in our inadequate knowledge of the concentrations which define the zones of nutritional adequacy or inadequacy. However, a great amount of research has provided more definite knowledge of the desirable blood levels of this constituent than is available for any of the other vitamins. Gyorgy[44] summarized current opinion in stating that "the normal level for ascorbic acid in human blood plasma is 0.7 mg. per 100 ml." He reported that lower blood levels may be interpreted as indicative of insufficient intake or increased body demand, as in infection, an actual deficiency, or tissue under-saturation. Youmans[45] states that normal concentrations of vitamin C range from 0.7 mg. per 100 ml. of serum upward, with 1.2 mg. per 100 ml. or better being commonly observed in well nourished subjects. He considers values in the range of 0.4 to 0.7 mg. per 100 ml. as constituting the borderline region and values below 0.5 or 0.4 mg. to be definitely deficient. Similar opinions are expressed by Farmer[46] and others,[12, 29] although Farmer warned that the finding of a level of 0.0 to 0.4 mg. per 100 ml. need not be interpreted in any individual as being indicative of severe deficiency unless the low level is found in repeated examinations.

A striking illustration of the effect of dietary pattern on blood serum vitamin C levels was found in a child caring agency where children live in groups of nine to twelve in individual cottages. Evening meals are served in a common dining room but the house mother in each cottage is responsible for the planning and preparation of two meals each day and variations in dietary pattern might be expected.

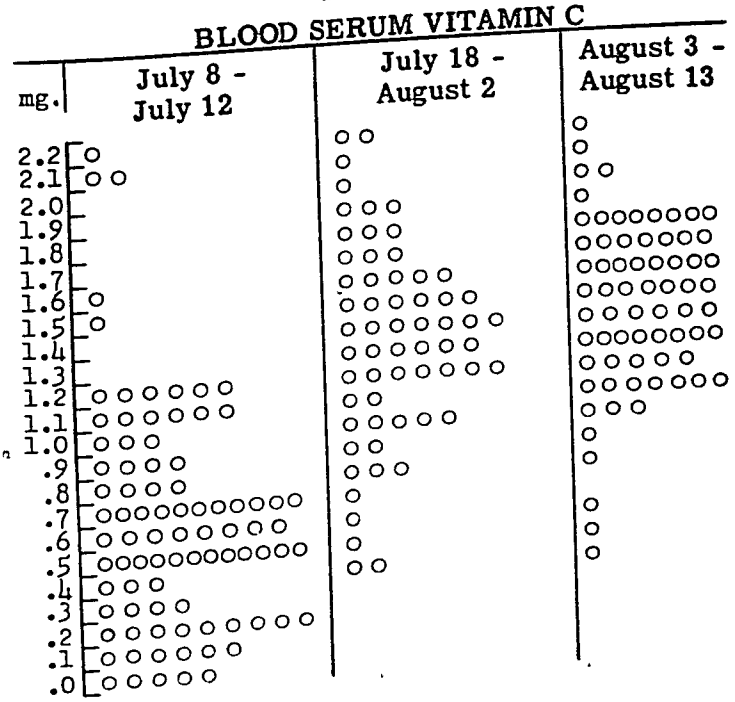
In cottage A, breakfast menus generally included canned orange concentrate and the luncheon menu often provided fruit salads. In contrast, the children in cottage B were served orange concentrate infrequently because the house mother, who had no training in

FIGURE 3

Fasting Blood Serum Vitamin C Levels for Two Groups of 10 Children Each Living in an Individual Cottage, on Three Successive Days

Values in milligrams per 100 milliliters

Day	Cottage A		Cottage B	
	Mean	Range	Mean	Range
1	1.13	0.92–1.33	0.12	0.02–0.28
2	1.06	0.54–1.52	0.17	0.00–0.34
3	1.05	0.66–1.51	0.12	0.05–0.23



nutrition or dietetics, believed high intakes of milk were all-important for children and encouraged consumption of it in preference to citrus fruit or juice.

Blood samples were collected three successive days from each of the 10 children in each cottage. The mean level of blood serum vitamin C (Figure 3) for each day was considerably higher for the occupants of cottage A than for those in cottage B. The ranges for the children in cottage A also were much higher than those for the children in cottage B. The values for vitamin C in the serum of the group of children in cottage B might be questioned as representative of well nourished children.

Figure 4 portrays the changes in fasting blood serum vitamin C levels for those children from whom samples were obtained two or more times at Bay Cliff Health Camp. The initial levels show that the majority of the children (59 of 88) had less than 0.8 mg. of vitamin C per 100 ml. of blood serum; values for 27 were indicative of deficiency (0.0 to 0.5 mg. per 100 ml.); and values for 32 indicated a prescorbutic state (0.5 to 0.8 mg. per 100 ml.). Only 21 had unquestionable levels, ranging from 1.0 to 2.3 mg. vitamin C per 100 ml. of serum, and only 29 had concentrations of vitamin C considered adequate to sustain health and provide a margin of safety for rapidly growing children.[4] Since the blood samples for the initial determinations were obtained after the children had been in camp for several days and the response to increased intakes of vitamin C is known to be extremely rapid, it is likely that many of the children had even lower levels of the vitamin in their blood serum prior to admission to the camp.

The vitamin C studies in the middle and final weeks of camp provided a striking example of progressive improve-

FIGURE 4

Fasting serum vitamin C levels of children at Bay Cliff Health Camp

ment and stabilization in the nutritional status of children in response to improved dietary environment. After three to four weeks at camp (Figure 4), determinations for 61 children showed none with a serum vitamin C value below 0.4 mg.; 51 with values of 1.0 mg. or more; and 10 below 1.0 mg., of which only 5 were below 0.8 mg. per 100 ml. Determinations during the final two weeks at camp showed 64 children to have levels of blood serum vitamin C at or above 1.0 mg. per 100 ml.; 2 with levels of 0.8 and 0.9 mg.; and 3 with 0.4 to 0.6 mg. per 100 ml.

Weight gain is not as reliable a criterion of satisfactory growth conditions for the growth and development of children as is a thorough evaluation of nutritional status, for even with food intake sufficient to allay hunger and produce weight gain, the diet may not contain essential substances in amounts sufficient to maintain in the blood and body tissues the levels requisite to health, much less provide reserves for periods of stress. If the body has become conditioned to an inadequate diet, weeks may be required for nutritional conditioning, with the accompanying attainment of the physiological adjustment of body tissues and fluids necessary for nutritional stability and normal growth. Although a number of the children in the present study arrived at camp with supplies of commercial vitamin products (unused while there), the data indicate that either they had not been taking the synthetic products for sufficient lengths of time or that the substitutes for proper food were not adequate. For the children studied at Bay Cliff Health Camp the results of determinations of vitamin C in their blood serum provide a notable illustration of beneficial physiological effects of proper food and healthful environment, as well as of the rapidity with which nutritional conditioning may be achieved and nutritional stability attained.

American Cancer Society Raises Record Sum

According to a recent report of the American Cancer Society, New York City, the proceeds of the 1948 campaign stand at $13,087,178, which is the largest sum ever raised by the American Cancer Society for its program, which includes educational campaigns for early recognition, the development of treatment facilities, and research.

Welfare Measures and Their Effect upon the Family*

BAILEY B. BURRITT

Executive Secretary, Health Maintenance Committee, Community Service Society, New York, N. Y.

MY experience in welfare work goes back to the first decade of the century. In New York City at that time there was little or no welfare work for families in their own homes at public tax-supported expense. There was no relief for families in their homes, except a trickle of relief afforded by voluntary agencies. There was no workmen's compensation to prevent the breakdown of family life through accidents. There was no unemployment insurance and no old age security through so-called insurance.

The outstanding fact was that families would break up. Children were herded into institutions for dependent children. The aged without means of support went to almshouses and the chronic sick to chronic hospitals. Most families in distress economically through death, illness, accident, protracted unemployment, or other family economic distress, struggled along preferring to remain in distress even at the expense of increasing the number of deaths, the volume of illness, undernourishment, and gradual deterioration, rather than accept proffered assistance of breaking up the family through institutionalizing all but the able-bodied members capable of self-support.

The results were disastrous. Confronted with this threat to the very foundations of family and social life, social morality and social conscience awakened and began to attack the problem. First came workmen's compensation. This was followed during the next two decades by legislation providing allowances for children in widows' families, by old age allowances and the gradual extension of other forms of relief to the blind, the sick, etc.

Then came the depression of the third decade, with its resultant breaking down of the traditional restraints of the old poor law and the opening of the gates to implementing modern concepts of relief. It went further and moved toward the prevention of poverty through social security provisions for unemployment and old age. Meantime the social awakening was leading to more adequate compensation for work performed and the great improvement that this brought to family life through an improved standard of living.

All of this meant an extraordinary change in social life. No longer do we see family life in any significant amount broken up through the disaster of death, sickness, accident, unemployment, and other misfortunes to the economic stability of family life. A very considerable percentage of families have been removed completely from that marginal group which were plunged into poverty as soon as adverse social and economic circumstances overtook them. Social services in a more limited sense

* Discussion presented at the Round Table on The Family as the Unit of Health, in connection with the Twenty-fifth Annual Conference of the Milbank Memorial Fund, November 17–18, 1948. The proceedings of the Round Table will be published in a single volume by the Milbank Memorial Fund.

of the so-called public and voluntary welfare agencies are freed from giving attention to this large group of families. This has made possible a much more adequate service to the more limited number of families coming to them for care. Social security approaches to these problems, supplemented by the combination of voluntary and publicly supported social services, have not only made the break up of families unnecessary, but have in addition reduced the volume of deaths, sickness, and deterioration in the physical mental, and moral life of families. Children in disadvantaged families are now better cared for, better fed, better educated, have less sickness, and fewer of them die.

We are now at the point where we are raising the question of where we should go from here. We are observing with much interest the experience of our neighbor, Canada, in granting allowances to children of specified ages irrespective of the economic status of the family, thus helping to tide over that most difficult period in the economics of family life when there are additional members in the family to be supported from the earnings of the breadwinner.

We are observing the interesting experiment in Manitoba and Saskatchewan, Canada, of extending home and hospital medical care to families through special and general revenues of the government without direct charges to them. We are students of the accumulating experience of Great Britain with their National Health Service Act which went into effect on July 5, 1948. We are fortunate in having this experience and that of other countries which have extended security and welfare provisions further than we have in New York to draw upon before making further modifications in our own program.

It will be seen from this silhouette of trends in the last few decades that welfare measures have modified social life and the functions of welfare services enormously. Social welfare and public health have become politically important. All parties and all political candidates in their platforms and definite programs make reference to further improvements in welfare and health services. Good welfare and health programs have become good politics. And the impact of this upon family life has been enormous.

These significant developments leave us with the question of how far and how rapidly is it wise to go in extending present welfare services. This is now the subject of active debate. How far can the State go in extending welfare work and the so-called security to all families without weakening human efforts to better themselves? How far is it possible to go before diminishing returns appear in national productivity and national income and the leveling off or reduction of the average standard of living? These are some of the unanswered questions which confront us as we study next possible steps in the development of welfare work for families.

A Pattern of Local Services in the Saskatchewan Health Program*

FREDERICK D. MOTT, M.D., F.A.P.H.A.

Chairman, Saskatchewan Health Services Planning Commission
Regina, Saskatchewan, Canada

IT is my privelege to give you a brief account of a local unit of health administration in Saskatchewan, a unit with an advanced and in many respects unique program—the Swift Current Health Region. There is no other unit of its kind in North America, in which all residents are eligible, on a tax-supported basis, for basic public health services, virtually complete medical services, hospitalization, and dental care for children. No one would claim that this program is ideal in organizational structure or in services provided, but it must command our attention as a courageous pioneering effort with spreading influence.

As an outgrowth of Dr. Henry E. Sigerist's health survey in 1944,[1] the populated southern half of Saskatchewan, with a population of 840,000, has been tentatively divided into twelve so-called health regions as a basis for the coördinated development of essential community health services. Of these, six now have active public health programs and one of the six, the Swift Current Region, has extended its services into the medical care field. The health region is built on the concept of the natural trading area surrounding a major trading center. It is composed typically of from three to five smaller trading areas, each with its principal center, and these become public health districts within the health region. As might be expected, the definition of district and regional boundaries has been largely the outgrowth of intensive hospital planning.

Doubtless the lack of county organization in Western Canada has facilitated the establishment of logical, geographic units of health administration. But the merging of a large number of local municipalities into one health region presents its own problems. In addition to its cities, towns, and villages, Saskatchewan has vast agricultural districts divided into more than 300 self-governing rural municipalities, recognized in health circles for 30 years for their "municipal doctor" plans. The health region draws into one channel the remarkable drive which has characterized organized farming areas in the province over the years as they have fought against odds to obtain medical services.

The Swift Current Region is in the southwest corner of Saskatchewan, bounded by Alberta to the west and Montana to the south. It includes one city, Swift Current, with a population of 7,200, 6 towns, 32 villages, and 38 rural municipalities. The region's 55,000 people are spread out over an area little smaller than the combined area of Massachusetts and Connecticut. There are less than 5 persons per square mile, in contrast to 546 in Massachusetts. In this, low-moisture and chron-

* Presented before the Medical Care Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

ically poor-crop, wheat farming and ranching territory, a complete health program faces odds which accentuate the significance of its success.

The visitor to the modern Regional Health Center in Swift Current finds not only clinic facilities and the offices of the Medical Health Officer and his senior staff, but also a beehive of some fifteen clerks and stenographers responsible to the full-time Secretary-Treasurer of the Regional Health Board. At this stage there is not complete integration of the public health and medical care programs administered by these two staffs, but as they work side by side, more effective coördination is constantly being achieved.

The program of more or less traditional public health services represents largely a decentralization of what remain primarily provincial functions. The Health Officer and his staff are employees of the Provincial Department of Public Health. Yet, one-third of the public health budget comes from the Region and increasing authorities are being vested in the Regional Health Board.

So far as various medical services are concerned, the Regional Board has almost complete freedom of action and responsibility, subject to the approval of the Provincial Government. The members of the Board look to the Health Officer for advice, but they administer the medical care program through their own Secretary-Treasurer and staff.

The Regional Board, which is a board of health for public health purposes and a "board of directors" for the medical program, is a powerful group of twelve community leaders. They are elected by District Health Councils in each of the four public health districts, on the basis of one Board member for roughly 5,000 population. Each district health council is composed of representatives of every municipal council in the district. This democratic structure seems effective in providing a two-way channel from the local municipal council to the Regional Health Board whereby local views may be considered at top level and, in turn, Board actions may be interpreted locally. These processes are facilitated by the holding of District Health Council meetings throughout the year, with Board members in attendance, and by the annual joint meeting of all ninety-four members of the four District Health Councils, together known as the Regional Health Council.

Basic public health work has become well established since it was placed on a full-time basis in February, 1946. Despite personnel shortages, an active program is in full swing. Serving the population of 55,000 under the direction of the Health Officer, there are 9 public health nurses, 3 sanitary officers, a health educator, and a regional registrar of vital statistics. The nurses and sanitary officers work out from three district offices as well as the Regional Health Center in the main district. It is hoped that two of the district offices will soon be superseded by District Health Centers located in the hospitals in the two towns concerned. This would foster the day-to-day coördination of diagnostic and therapeutic services and the activities of public health personnel in such field as communicable disease control, maternal and child health, mental hygiene, and health education.

In large units of health administration, covering vast stretches of sparsely settled prairie, health officers are primarily planners and administrators. Their role is based on the premise that the family doctor should become responsible for personal preventive services. Even when mass measures are called for, as in well baby clinics or in school health work, provision is made for employing local physicians to provide the service.

When the voters in southwestern Sas-

katchewan rolled up a large majority for the establishment of the Health Region, they were voting not only to obtain full-time public health services, but to tax themselves to provide medical and hospital services. July 1, 1946, was the "appointed day" and the medical program started on schedule. The Swift Current Board would be scornful of anyone listing the many reasons why compulsory health insurance cannot or should not be adopted. Wanting health insurance, they organized it and set it in motion, and they like what they have.

Swift Current's program of health services has gone through certain evolutionary changes during its 28 months of operation, but time permits only a description of the program as it operates today.

Every resident of the region is eligible for services, provided he is not in an exempt class, such as old age and blind pensioners, mothers' allowance recipients, and certain other public assistance recipients already entitled to medical care through a separate provincial program. Also exempt, are various Dominion Government beneficiaries. Indigent families for whom local municipalities are responsible participate fully in the regional program, their tax being paid by the municipality of residence. The region's program covers some 51,000 of the entire population of 55,000.

The principal service is medical care, including all medical, surgical, and obstetrical services on a free choice basis within the region, and by referral to specialists outside the region. The physicians may impose mileage charges and patients referred outside the region are occasionally charged the difference between the fee paid by the region and the specialist's fee. Otherwise, there are practically no restrictions in medical benefits.

The Regional Board employs a full-time radiologist to serve the whole region. While most of his work is done at the Swift Current Union Hospital, he makes periodic visits to the principal district hospitals. The Board is now supporting a plan to engage a pathologist to serve their own and two adjoining regions.

Perhaps the most popular service is the dental care program for children under 16. Four full-time dentists with assistants, using both fixed and mobile clinics, are reaching thousands of children who had seldom if ever had proper dental care.

Another benefit is hospital outpatient service, including diagnostic procedures and physiotherapy. The region provided inpatient hospitalization from July through December, 1946, but was able to drop this benefit with inauguration of the province-wide, tax-supported hospitalization program on January 1, 1947.

The medical care program is financed by a personal tax, a land tax, and provincial grants. The compulsory personal tax is $15 a year for the first member of a family, $24 for two, $30 for three, and $35 for four or more. In addition, all property owners pay a 2.2 mill land tax which produces one-fourth of the revenue raised by the region. Provincial grants which yield the remaining 9 per cent of total revenue cover half the cost of the three special services—radiological, dental, and outpatient services.

The 1949 budget totals $695,000, or about $13.65 per capita, not including $1.20 per capita for public health. Of the $13.65, about $10 per capita is for physicians' services, including referrals outside the region.

Physicians within the region are paid on a limited fee-for-service basis from an annual fund of $420,000. In 1947, before this limitation on expenditures was agreed upon, the region's physicians received on a discounted fee basis, a

total of $410,850. The average gross income per physician was $1,061 per month, or--on an annual basis--$12,739, not counting other sources of income.

A review of the services provided reveals that the office call rate is low, the home call rate is very low, and the hospital case and day rates are quite high. Thus, preliminary data reveal an office call rate for 1947 of about 1.5 per person, a home call rate of 0.2, and a hospital call rate of 0.8, or a total of 2.5 physicians' calls per person annually. This is very close to the 1942–1944 rate of 2.6 calls recorded in the tax-assisted "Experimental Health Program" sponsored by the U. S. Department of Agriculture in seven rural counties, but it falls considerably short of what we expect from group practice prepayment plans in urban communities.[2] Hospitalization data are not yet available by health region, but in 1947 under the Saskatchewan Hospital Services Plan, there were 156 hospital discharges per 1,000 throughout the province[3] compared to an average Blue Cross admission rate of 122 the same year.[4] The Saskatchewan program furnished 1,565 days of care per 1,000, not counting undischarged cases, compared to a Blue Cross average of 969 days per 1,000.

A high volume of hospital care compared to other services is characteristic of sparsely settled territory when the number of doctors is low and the supply of hospital beds is reasonably adequate. Since the Swift Current program started, the number of physicians in the region has jumped from 19 to 33, but there is still a ratio of one physician to 1,650 people. On the other hand, five new hospitals have opened their doors in the last three years, giving a region-wide ratio of 5.2 beds per 1,000 by rated capacity in the fourteen hospitals within the region. The whole nature of medical practice on the prairies has changed in the last twenty years or so, as patients have become accustomed to go to the doctor and to the district hospital rather than call the doctor to the home.

Here, then, on the northern Great Plains, we have a "pilot plan" offering a large measure of health security to a population group which is all too familiar with economic adversity. The people like the program and the physicians are satisfied with it. Recently, Dr. A. D. Kelly, Assistant Secretary of the Canadian Medical Association, analyzed the program in the light of the Principles Relating to Health Insurance enunciated by the Association in 1944. He concluded that the region's universal coverage contributory program was essentially consistent with these Principles, except that practising physicians were not in positions of administrative responsibility either in the Health Region or in the Provincial Health Services Planning Commission. Despite this, Dr. Kelly conceded that the regional administrative arrangement "has worked with remarkable satisfaction."[5]

The program is not static. The Regional Board and the Health Officer, in close consultation with professional and lay groups and community institutions, are constantly exploring new avenues of accomplishment and of coördination. Physicians are beginning to insist that their patients attend well baby and preschool clinics. Public health nurses are relying heavily on the assistance of private practitioners. A healthy attitude of mutual dependence is spreading. Coördination of community and personal health services in the field is fostered centrally by virtue of the fact that all administrative matters, relating to any aspect of the program, are channeled through the Director of Regional Health Services in the Provincial Department of Public Health.

The Regional Board is taking an in-

creasingly active interest in planning improved hospital and diagnostic facilities at regional and district centers. They are fully aware of personnel problems, too, ranging from the chronic shortage of nurses to gaps in their physician resources, and their latest action was to guarantee a doctor $6,000 to move into a remote area of the region. It has been particularly gratifying to see the Board's steady swing to the conviction that having two specialists in surgery and one radiologist in the region does not spell adequacy in specialist resources for 55,000 people. This conviction has not been un-influenced by the Board's annual expenditure of $75,000 for specialist care beyond the borders of the region. They now have their minds set on building a group of full-time consulting specialists who would handle cases by referral from general practitioners and would also visit principal district centers regularly. Characteristically, they are tackling this rather touchy objective in full consultation with their Medical Advisory Committee, sensing the soundness of an evolutionary development through common agreement.

Many problems still await solution, of course, in an evolving program of this kind. What is the proper balance in public health authority as between the province, the region, and its constituent municipalities? When a province-wide program of health insurance is established, what degree of decentralization may properly and wisely be permitted? Must the relationship between basic public health services and medical services remain one of coördination, or is complete integration possible? Can the organization of rural health services, as a quality measure, be accomplished through inducements and education without coercion?

Of perhaps more immediate concern, what would a continued drought like that of the 1930's do to a program financed largely through a flat, personal tax? Whatever the answer, there are signs that this worry may shortly be ended. The Dominion Government has just embarked on the first stage of a national health program, which is frankly preliminary to a second stage, Dominion assistance to the provinces to enable them to finance comprehensive health insurance. Toward the first stage, involving the strengthening and extension of public health work, hospital construction, and general health planning, the Dominion is granting $30,000,000 annually to the provinces. This sum, on a per capita basis, is about double that granted by the federal government in the United States for similar purposes. These grants are for general public health work, tuberculosis control, venereal disease, cancer control, mental hygiene, crippled children, professional training, public health research, and—as stated—hospital construction and general planning. The Dominion grants mean improved programs and more stable programs. If they have been criticised by major political parties in Canada other than the party in power, it is because they do not go far enough.

Compulsory health insurance lies just around the corner in our neighboring nation to the north. And the Swift Current program is proving that it will work.

BUILDING OUR DEFENSES AGAINST INFLUENZA

PREDICTIVE epidemiology is always a hazardous business; but with the first half of the winter season gone—and no unusual prevalence of the disease reported in the United States—it did not look as if 1948–1949 were to be an "influenza year." Now, however, comes disquieting news of widespread upper respiratory disease on the continent of Europe. Whether this is influenza or not, whether it will cross the ocean or not, we cannot, at this writing, know. In any case, there is ample reason for perfecting our defenses against this disease. In the spring of 1918, there were distinct localized outbreaks which may reasonably be assumed to have been forerunners of the great pandemic of the fall. If such outbreaks occur this spring, their careful study will be of prime importance.

In 1918, there was very little we could have done in the way of control, even if the whole future time schedule of the pandemic had been released in advance. Today, the picture is a different one. We know that preventive immunization is a powerful weapon in the control of influenza; but we also know that it is a highly specific weapon and that the vaccine which controls one "type" of the disease may be practically ineffectual against another "type." We have the scientific basis for real protection against this appalling malady, but success will depend entirely on our knowledge of the particular strain of virus concerned in a given outbreak and our ability to prepare a specific vaccine in time.

It was for these reasons that the 4th International Congress for Microbiology in 1947 proposed a world program of collaboration for the control of influenza; and that—later in the same year—the Interim Commission of the World Health Organization established an Interim Influenza Committee in London. Early in 1948, the Strain Study Center now at Long Island College of Medicine was recognized by the Surgeons General of the U. S. Army, Navy, Air Force, and Public Health Service as our National Center to coördinate work in this country and to coöperate with the World Health Organization in its global task. This center is "(1) to serve as a clearing house in the United States for the receipt and dissemination of information regarding influenza and the virus responsible for the disease; (2) to coördinate the work of the diagnostic 'watch stations' needed in the United States for the laboratory identification of cases of influenza

and the isolation of new strains of the influenza virus; and (3) to aid in arranging conferences looking toward possible improvement of influenza vaccine by the incorporation of newly isolated strains of virus."

To work with this National Center, a chain of some 60 federal, state, and local laboratories, widely distributed through the United States and its territories, have been designated as participants in the program. These laboratories have been listed by J. T. Culbertson in the January issue of this *Journal*.[1] About half of these laboratories are prepared only to make agglutination-inhibition tests on the serum of patients with suspected influenza. The other half are also equipped for isolation of the specific virus. When a No. 1 station reports elevated titers of influenza antibodies for any outbreak of respiratory disease, the nearest No. 2 station will send into the affected area a team of investigators expert in the isolation of the virus. Once a strain of virus has been isolated, it will be sent to the National Influenza Strain Study Center on Long Island for antigenic analysis.

This is a sound and well articulated program of defense against influenza. Its execution should give us full knowledge of the presence of the enemy and open real possibilities of effective defense. Success, however, will depend on the full coöperation of health officers and of physicians throughout the land. Only by prompt reporting of all outbreaks of respiratory disease, and after immediate transmission of reports to the Influenza Information Center in the Division of Research Grants and Fellowships at the National Institute of Health in Washington, will the wheels begin to turn. This Center will alert the No. 1 station and the process described above will begin to function. Primary responsibility, however, must rest with the local health officer. Prompt notification of outbreaks of respiratory disease this spring may save many thousands of lives — if an epidemic of virulent influenza should visit us in the future.

COMMERCIAL EXPLOITATION OF GLYCOL VAPORIZERS

NUMEROUS articles on the use of glycol vapors for the prevention of acute respiratory diseases have appeared in the lay and semiscientific press during the past year. The general import of this publicity is that we now have a panacea for the prevention of colds. Since everyone catches colds, and colds result in more loss of time to industry than any other single cause, the desire on the part of the public to make use of such an apparently simple preventive method is natural. What the above mentioned writers fail to point out and, unfortunately, this is true even of one popular article which appeared in an official medical publication, is that upper respiratory infections are transmitted in many ways other than through the general atmosphere of occupied spaces. Infection from hands and handkerchiefs and sneezing cannot possibly be controlled by general aerial disinfection of occupied indoor spaces. No matter how completely the air may be disinfected, people will still catch colds.

The recent uncritical publicity has been accompanied by a nation-wide commercial exploitation of glycol vaporizing devices. These are being advertised for essentially indiscriminate use in homes, offices, schoolrooms, and almost any place where two or more people may congregate. The devices being offered for sale

vary from small cans or boxes that may be placed in the corner of a room or on a table, to vaporizers which may be installed in the ducts of large ventilating systems. Some of these devices have been designed by reputable engineers who are working to supply satisfactory apparatus; others are being promoted by individuals and concerns apparently quite ignorant of the scientific principles involved. None of these devices has yet been certified as to its effectiveness by the Council on Physical Medicine of the American Medical Association or any other authoritative body. Since health officers, school physicians, and practising doctors throughout the country are being deluged with requests for information and advice regarding glycol vapors, it is appropriate to review briefly the evidence on which their use is based.

Two years ago the status of methods for the control of air-borne infection was critically reviewed in a report by a subcommittee of the A.P.H.A.[1] This report emphasized that glycol vapors, particularly those of triethylene glycol, had a marked bactericidal effect on many types of air-borne bacteria and viruses when sprayed into experimental chambers. This effect is greatest when relative saturations of the vapor exceed 50 per cent and when the relative humidity is from 25 to 50 per cent. At lower relative saturations and in drier or moister atmospheres the bactericidal effect is progressively diminished. An instrument called a glycometer or glycostat, which measures the relative saturation of glycol vapor in the air and which may be utilized to control the output of vaporizers, has been developed for experimental uses but no such instruments are as yet available commercially.

The degree of aerial disinfection obtained in experimental trials of glycol vapors under field conditions in hospital wards, army barracks, and industrial establishments may be less marked than that achieved under experimental laboratory conditions. The glycol vapors are largely noneffective on bacteria-laden dust particles. Except in completely air-conditioned environments or when glycostats are used in conjunction with vaporizers it has been difficult to maintain adequate concentrations of the vapor. Constant engineering supervision has been necessary. Concomitant measures to control dust are imperative to achieve substantial aerial disinfection.

Only a few experimental trials of glycol vapors for the prevention of acute respiratory diseases have been reported. The results vary from a marked reduction of infections among bedridden patients in a hospital ward to inconclusive effects in other instances. Too few studies have been conducted in sufficiently large population groups, under sufficiently well controlled conditions and for sufficiently long periods of time to provide any basis for a conclusion regarding the effectiveness and practicability of glycol vapors for the control of acute respiratory infections.

Two years ago the subcommittee of the A.P.H.A. concluded:

> The available evidence strongly indicates that . . . glycol vapors are useful adjuvants to aseptic techniques in the reduction or elimination of air-borne infections in operating rooms, and in contagious disease and pediatric wards . . . The general use of disinfectant vapors in schools, barracks and in specialized industrial environments is not justified at the present time. There is great need for further carefully controlled field studies . . . There is no justification for indiscriminate use . . . in home, offices, or places of public congregation.

In the past two years real progress has been made in the development of vaporizing devices, but there has been essentially no advance in our knowledge of the effectiveness of these vapors in the prevention of acute respiratory diseases.

Until such knowledge becomes available, it is unwise to recommend the installation of glycol vaporizers except under carefully controlled experimental conditions. Present commercial campaigns of exploitation raise the real danger that the method may be discredited and that the rational development of this important field of air sanitation may be discouraged.

HOME CARE AT THE MONTEFIORE HOSPITAL

THE program for home care at the Montefiore Hospital of New York City, described in this issue of the *Journal* by Dr. Martin Cherkasky, is worthy of the serious consideration of our readers. The concept is not, of course, a new one; but it has perhaps never been developed with quite such completeness and success.

The program is designed for patients who — for one reason or another — do not require further hospitalization but do need continuing medical and nursing care. When preliminary study of a given patient indicates that the necessary domiciliary care can be provided, with advantage to the individual concerned, the patient is transferred to his own home and the hospital supplies any or all of the following: medical service, at any hour of the day or night, with all necessary consulting specialist consultations; social service from the regular hospital staff; nursing care and instruction by the staff of the Visiting Nurse Service of New York, under a contract plan; housekeeping service, if indicated, to relieve the housewife for care of the patient; transportation to and from the hospital for special examinations or treatments; all necessary medication and appliances; occupational therapy and physical therapy in the home.

Analysis of over 23,000 days of patient care shows a cost of $3 per patient day for this type of treatment as compared with $12–$15 per day for intramural care. It should be noted that the cost of food and shelter is shifted to the family. It is also clear that the adoption of such a program does not mean a reduction of hospital costs, since the beds vacated by Home Care will be filled by other patients needing full hospitalization. The Montefiore plan has been made possible by grants from the New York Cancer Committee and the Greater New York Fund. The net potential saving of total community resources for meeting total community needs is, however, very great.

The program is presented by Cherkasky, *not* as a means of saving money; but as a method of providing better medical care for a specific group of patients. Under the plan developed at Montefiore the patient has not only the comfort of his own bed and the freedom of his own household regime, but a more personalized medical service when a doctor visits two or three times in his home than can be involved in the routine of ward rounds where attention is inevitably focused on new and critical cases. He receives not less adequate but infinitely better medical care; and to the doctors who participate, the program has brought an invaluable revelation of the social and psychological backgrounds of the lives of men and women who have hitherto been occupants of numbered beds on a ward.

The two essential factors in the success of such a plan are: (1) the careful selection of suitable cases; and (2) the ability of the hospital to provide the Home Care services listed above. At Montefiore, every patient considered for

Home Care is first studied by the physician to determine whether he is medically eligible; and, next, a careful social service checkup is made to determine the suitability of the home and the adequacy of the emotional atmosphere, on the part of both the patient and the family. About half the cases considered qualify on both grounds.

This program makes a contribution of major importance to the technology and to the philosophy of medical care. It is essential, however, to remember that its successful application depends on a high degree of hospital development, in the fields of medical staff, social service, nursing, physical and occupational therapy. It would be most unfortunate if so fruitful a concept were to be discredited by wholesale displacement of patients by hospitals which lack the facilities to carry the program out successfully.

HUGH S. CUMMING

THE death of Hugh S. Cumming on December 20, 1948—at the age of 79 years—removed one of the outstanding leaders of American public health. He was a member of this Association from 1914, became a Charter Fellow in 1922, served as Elective Councillor (1921–1922 and 1925–1931), and Executive Board Member (1929–1931); and was elected President in 1931.

Dr. Cumming was in the fullest sense a "career man" in public health. He joined the staff of the U. S. Public Health Service in 1894, within less than a year of graduation from the University College of Medicine at Richmond, and progressed steadily to his appointment as Surgeon General in 1920. In this latter post, he served until 1936, overlapping the terms of five Presidents of the United States. Under his administration, the Service grew from comparative obscurity to a bureau of far-reaching influence, employing more than 1,000 physicians. During this period, the maritime quarantine program of the Service was carried to completion, pre-immigration physical examinations were introduced at our Consulates abroad, a national leprosarium and national narcotic farms were established, and the work of the Hygienic Laboratory was greatly strengthened. Perhaps the most significant and outstanding service of this Surgeon General, which does not appear in the official record, was the discernment and vision with which he brought young men of ability and promise into positions of responsibility in the Service. Many of our leaders in subsequent years were selected and advanced in the Service by General Cumming.

Dr. Cumming was not only a wise administrator but also an excellent type of the Virginian gentlemen, with a flair for diplomacy. On the international stage, he served as President of the Office Internationale d'Hygiène Publique, as an active member of the Health Committee of the League of Nations, as a delegate to the Cannes Conference in 1919, and as head of an allied medical mission to Poland. His major interest, however, was in the Western Hemisphere, and he served for many years as President of the Pan American Sanitary Bureau, continuing in this post after his retirement from the Public Health Service up to 1947. He received decorations from seven Latin-American countries for the distinguished and generous service which he gave to this cause.

The American Public Health Association, the United States Public Health Service, and the general cause of public health in the Western Hemisphere continue to reap notable benefits from Hugh Cumming's leadership in the past. They will recall his name with grateful admiration in the future.

LETTERS TO THE EDITOR

TO THE EDITOR:

This letter is prompted by the recent excellent article by John B. Blake, "The Origins of Public Health in the United States." The following facts concerning public health in the prospective State of Hawaii may not be generally known and may be of interest to some of your readers.

1825. Action was taken against the "promiscuous immorality which had sprung up in the port of Honolulu . . ." This may have been the forerunner of a venereal disease control program which was quite highly developed in the '60's with dispensaries and hospital beds for syphilitics. *(Oxford Dictionary*—1862. "A syphilitic ward in the Queens Hospital at Honolulu.")

1839. Kamehameha III, on May 29, 1839, signed Hawaii's first quarantine law. "4. For the purpose of carrying into execution the above regulations, it shall be the duty of the several Governors, to set apart a Board of Health for each of the harbors of the Sandwich Islands. And such Board of Health shall have full power to enact such laws and regulations as may be necessary to protect the health of their several places. They (the governors) shall also appoint health officers . . ."

1850. December 16, 1850, Kamehameha, in privy council, established a Board of Health for the Islands.

1851. On May 8, 1851, the legislature confirmed the above action. Some subjects covered by the 19 sections of the law were: Powers of the Board members; nuisances; study of existing quarantine laws and framing rules regarding them; reporting of "malignant disease" and deaths; appointment of physicians to care for isolated patients; and power to make necessary regulations.

1854. The Minister of Interior was directed to appoint vaccinators for the several major counties.

1855–1862. The Minister of Interior includes in his report activities of the Board of Health.

1866 to the present time. The Board of Health has submitted annual or biennial reports.

The documents mentioned above are available at the Territorial Archives, Honolulu. They may represent one of the most complete records of early public health activity of any of the several states or territories.

TO THE EDITOR:

When one is honoured by a reference in the AMERICAN JOURNAL OF PUBLIC HEALTH one expects to be quoted correctly. May I point out that in Dr. Quinn's article on rheumatic heart disease in your issue of August, 1948, page 1078, I am credited with "the statement based on data collected some 30 years ago that rheumatic fever is 30 times as common in *industrial as in rural towns.*"

What I said was very different. "No disease has a clearer cut social incidence than acute rheumatism, which falls perhaps 30 times as frequently upon the poorer children of the industrial town, as upon the children of the well-to-do."

I most cordially agree with Dr. Quinn on the importance of Crowding.

This statement is probably still true in England, though the incidence has much lessened.

Clearing House on Public Health Salary Information

MANY CITIES INCREASE PAY RATES

Nearly two-thirds of 97 reporting cities of over 5,000 population increased the pay of some or all employees in the first half of 1948. Most of the other cities had granted pay increases in 1947, and several raised pay rates two or more times during the period from January 1, 1947, to July 1, 1948. These are the highlights of a pay rate survey of 20 standard positions in nearly 100 cities made recently by the Civil Service Assembly and the International City Managers' Association.

In 1947 cities tended to raise the wages of firemen, policemen, and certain labor groups, and let the pay of junior professional employees and certain skilled office workers lag behind. But during the first part of 1948 the discrepancy was narrowed, with more cities making pay increases for professional employees and office workers.

Thirty of the 97 cities reported that the pay rates of all employees were increased during the first half of 1948; 11 cities of 25,000 to 100,000 and 9 cities of 5,000 to 25,000 increased all pay rates.

Most cities increased pay by a flat amount per month, ranging from $5 to $25. Only 3 increased salaries by a flat percentage amount (5 per cent), and 4 adopted a higher pay schedule in connection with new position classification and pay plans. The survey entitled *Pay Rates for Selected City Jobs in July, 1948*, is published by the International City Managers' Association, 1313 E. 60th Street, Chicago, Ill.

SALARY DATA IN MUNICIPAL YEAR BOOK

The *Municipal Year Book* for 1948 has a chapter on Salaries of Municipal Officials. There are tables showing average, lowest, highest, and quartiles for the various types of administrators grouped by population of the cities. The value of the figures is limited for purposes of comparison between one administrator and another because the same cities do not report for each category. However, if you are a health officer in a city of 50,000 population with a salary of $4,500, it might help to tell your appropriating body that only 14 out of 56 cities of your size pay as little as that, and that 14 pay $6,880 or more, with $8,550 as the top.—*Municipal Year Book;* International City Managers' Association, Chicago. 1948.

SALARIES IN SCHOOL HEALTH SERVICE

Early in 1948 the Cincinnati public schools conducted a fact-finding inquiry concerning school health services in other cities of similar size. Replies were received from 36 cities of 43 queried, giving maximum salaries for medical and other specialized personnel engaged in school health services. This study might well be included in a library or bibliography of current salary data. Available from Cincinnati Public Schools, Department of Research, C. G. Tower, Director, 216 E. Ninth Street, Cincinnati 2, Ohio.

OHIO PROPOSES $5,000,000 INCREASE IN STATE SALARIES

The Public Administration Service has just recommended to the Ohio Salary Study Commission, salary increases totalling 5 million dollars a year for the 26,000 employees of the state. The Governor's salary would be raised from $13,000 to $20,000, that of chief administrative officers such as state audi-

tor, treasurer, attorney general, directors of education, health, finance, etc., from $6,500 to $12,000. This represents a rise of more than three-quarters. The salary plan further provides for salary ranges of five steps, with each step representing an increase of about 5 per cent over the preceding step. If the plan should go into effect for the state health officer, for example, it would have a far-reaching effect on the salary levels for other state health officers as well as for employees of health departments throughout Ohio.

In setting up the recommendations the report made it plain that the recommended rates were based upon the practices of other large states of the East, Mid-west and West. Recognizing the competition with private business, the study group made an effort to strike a medium between practices of other states and the salaries paid by private employers.

CONFESSION IS GOOD FOR THE SOUL

The *Oregon Health Bulletin* for December 8, 1948, says: "Although county health organization in this state is favorable in comparison to the national picture, present indications are that Oregon will enter 1949 without a single local health unit which meets basic acceptable standards recommended by the American Public Health Association.

"Principal reasons for the deficiencies are inadequate budgetary provision for recruitment of necessary staffs and salary scales unable to compete with private practice or compensation offered by the neighboring states of California and Washington.

"... Salary difficulties encountered in obtaining medical personnel can be seen in the fact that present remuneration to private physicians on the Pacific coast averages far in excess of any public health pay scale in Oregon."

This reënforces what has often been said, namely, if adequate salaries were offered, the shortages in public health personnel would largely disappear. The oftener this is said in so many words or in the terms of the Oregon *Bulletin*, the sooner will appropriating bodies recognize its truth and act upon it.

MEDICAL ECONOMICS PUBLISHES ANOTHER STUDY OF PHYSICIANS' INCOMES

Medical Economics, which is a national business monthly magazine for physicians, has completed its 6th quadrennial survey of incomes of physicians in private practice. The results are published in several issues of *Medical Economics*—September, October, November and December, 1948, and February, 1949—and will be continued in future issues.

The survey is based on a sample of approximately 5,000 physicians of 135,000 who received the questionnaire with their March, 1948, issue of *Medical Economics*. Data are shown with respect to gross and net income by states, by medical specialty, by years of practice, and a number of other classifications.

This first post-war study shows average net income of practising physicians more than doubled since the latest previous study in 1935. Although gross income figures are not at all comparable with salaries of public health physicians and net income figures not wholly so, this material should nevertheless be useful on a shelf of current salary data. It has not yet been decided whether the material will later be put together in a bound volume.

Medical Economics is published in Rutherford, N. J. It's subscription price is $3.50 per year.

STUDY OF SALARIES AND WORKING CONDITIONS OF NUTRITIONISTS

Questionnaires for a study of the economic status of dietitians, nutritionists, and food service managers were to be mailed to representative members of

the professions in February. The study is being conducted by the Bureau of Labor Statistics of the U. S. Department of Labor in coöperation with professional societies.

The survey is intended to find out the facts about earnings and working conditions of these persons and to learn what they think of their jobs. Together with similar studies of other professions, such as nursing, social work, and librarianships, it will give a picture of the comparative economic status and will provide much needed general information on the earnings and working conditions of the professional workers in the United States.

In announcing the study, Ewan Clague, Commissioner of Labor Statistics, urged all persons receiving questionnaires to answer them promptly. All replies will be entirely confidential and anonymous, and will be used only to prepare a summary report on economic conditions in the profession.

A.P.H.A. Vocational Counseling and Placement Increases Activity

Franziska W. Racker, M.D., M.P.H., who serves on the A.P.H.A. staff in charge of the Vocational Counseling and Placement Service in the New York office, has reported on her activities for the past year. Of particular interest is the comparison between the demand and supply of professional services in public health as manifest during the Annual Meeting week of the A.P.H.A. in the last two years.

In October, 1947, at the 75th Annual Meeting of the A.P.H.A. in Atlantic City, 52 employers interviewed the Service and a total of 69 candidates appeared who were interested in placement. In November, 1948, at the 76th Annual Meeting of the Association in Boston, 89 employers registered with the Service and only 38 candidates.

The following table shows the relationship of demand and supply in one week's registration.

It should be noted that the Association does not undertake to register public health nurses, believing that this is a special function best handled by specialized agencies.

Employers and Candidates Interviewed in Boston at the Vocational Counseling Booth November 8–12, 1948

	Employers		Candidates

Revised Criteria for Accreditation of Public Health Courses

The Criteria for accreditation of institutions for the degree Master of Public Health (M.P.H.—D.P.H. in Canada) and the degree Doctor of Public Health (Dr.P.H.) for the academic year 1949–1950, as recommended by the Committee on Professional Education and approved by the Executive Board, are printed below. In comparing the new Criteria with the Criteria on which the accreditation of schools for the academic year 1948–1949 was based, two changes will be noticed. The new Criterion No. 3 raises the old standard of a minimum requirement of six full-time senior faculty members to a new standard of eight, of which four must be primarily responsible to the administration of the school (previously three). This new requirement is already met by all ten schools which are accredited for 1948–1949.

The new Criterion No. 12 for the Dr.P.H. degree will make it possible for the schools to accept for the Dr.P.H. degree unusually well qualified persons without a prior doctoral degree, while the old Criteria stipulated that such students must hold a prior doctoral degree.

Criteria for Institutions To Be Accredited for the Degree of Master of Public Health (Diploma of Public Health in Canada) and for the Degree of Doctor of Public Health, for the Academic Year 1949–1950 *

Criteria for Both Degrees

The Institution

1. Any institution to be accredited must be a member of the Association of American Universities, or present evidence that it may reasonably be considered as qualified for such membership.
2. The school, faculty, or council administering courses in public health must have such practical autonomy that requirements for the degrees are effectively controlled by the public health faculty.
3. The teaching of public health must be under the direction of a full-time teaching faculty which must include, in addition to assistant professors and others of lower rank and in addition to part-time appointees:
   a. One member of professorial grade as director of the school or department, and at least three other members of professorial or associate professorial grade—all four primarily responsible to the administration of the school, and
   b. At least four other members of professorial or associate professorial grade, either primarily responsible to the school or giving full time to the university and carrying specific major responsibility for teaching and research in the school. Such a minimum faculty could provide for a body of graduate students in public health totalling not more than approximately thirty such students.
4. The school or department must have an assured minimum basic income adequate for its teaching and research functions and for meeting the various criteria outlined. Such income should be construed to include income from endowment of the school, contributions made from general university funds, and grants made over a period of at least five years from sources outside the university.
5. Proper housing must be available, including

* Revision adopted by the Committee on Professional Education of the American Public Health Association, November 8, 1948. Approved by the Executive Board November 29, 1948.

lecture rooms, seminar rooms, and adequate laboratory facilities for the teaching of subjects in the field of microbiology, including microscopes, culture media, apparatus, etc.; for the teaching of vital statistics, including calculating machines for student use, and apparatus for chart-making, with tabulating machinery accessible for demonstration purposes, and for the teaching of sanitary engineering, including laboratory facilities for the examination of water and sewage and for the demonstration of the basic principles of hydraulics.

6. Library facilities are essential to the extent of at least 3,000 volumes in the general field of public health, including such special topics as epidemiology, microbiology, vital statistics, sanitary engineering, medical economics and medical sociology, nutrition, and the like, and current periodicals (not including health department reports) to the number of at least 50 in the fields mentioned above.

7. There must be available conveniently located administrative units of public health services which can be utilized for observation and criticism in the basic courses for the Master of Public Health, and which are of sufficiently high quality to make such observation fruitful.

Criteria for the M.P.H. Degree

The Course

8. Candidates to be admitted for the degree of Master of Public Health (Diploma of Public Health in Canada) may be either:
   a. Holders of the degree of M.D., D.D.S., or D.V.M., or equivalent degree, from an acceptable institution; or
   b. Holders of the Bachelor's Degree with adequate training in mathematics and the natural sciences, including chemistry and biology, and also qualified in some professional capacity to pursue education in public health.

   The latter qualifications may normally be fulfilled either by
   x. Professional academic qualifications in engineering, public health nursing, education, or some other field of public health representing the equivalent of at least one year of academic work in addition to the completion of a four years course leading to the Bachelor's Degree;
   y. or experience (normally not less than three years) in some field of public health practice or in teaching of a type acceptable to the school.

9. The length of the course shall be not less than one academic year of 32 weeks.

It is highly desirable that the candidate shall have had practical public health experience in the form of supervised field service or in a position involving the exercise of substantial initiative and responsibility. This experience should preferably be obtained prior to entrance into the school. In some schools, candidates not so equipped on entrance are required to complete three months of practical work in the field before receiving their degree.

10. The following courses are among those generally offered in schools of public health:
    a. Public Health Practice (Administration)
    b. Sanitation
    c. Microbiology
    d. Vital Statistics
    e. Epidemiology
    f. Physiological Hygiene
    g. Nutrition
    h. Public Health Nursing
    i. Health Education
    j. Social and Economic Factors Influencing Health (Economic Factors in Health)
    k. Mental Hygiene
    l. Public Health Law
    m. Industrial Hygiene
    n. School Health
    o. Maternal and Child Health
    p. Tuberculosis
    q. Venereal Disease
    r. Dental Health
    s. Hospital Administration

It is believed that it would be highly undesirable to make standard requirements with regard to any particular courses of instruction. It does seem important, however, that the student—at some point in the M.P.H. course, or prior to that course—shall receive instruction in the following basic fields:

A. *Basic Public Health Sciences*
   (1) The nature and functioning of the human organism, and the personal behavior which influences its well-being, including nutrition and mental hygiene.
   (2) The nature and behavior of various forms of parasitic life, including

viruses; their interaction with the human body as demonstrated by clinical and immunological reactions; the modes in which such microörganisms are transferred from host to host in the course of their epidemiological history; and the ways in which such dissemination may be controlled.

(3) The physical environment as it influences health, including not only the classical problems of environmental sanitation, but also those relating to housing and industrial hygiene.

(4) The social and economic factors which influence the health of the individual and of the community, and the influences of sickness on the social and economic status of the individual and the community.

(5) The nature and sources of quantitative information bearing on the health of the people, and its numerical presentation and analysis.

B. *Public Health Practices*

(6) The principles of applying the basic sciences listed above to community health and welfare. This involves the elements of sound public administration as applied to official and voluntary health agencies, including office management, budget making, personnel relations, and public health law; and includes also the wide field of public relations as influenced by health education and community education.

11. There must be opportunity for advanced specialization in one or more of the fields listed under 10 above or in such special fields as tuberculosis control, venereal disease control, or tropical medicine. There will be little time available in the M.P.H. year for advanced specialization; but basic work can be conducted effectively only in an atmosphere of advanced scholarship and with the essential stimulus which comes from the conduct of productive research by the faculty and advanced students.

CRITERIA FOR THE DR.P.H. DEGREE

12. Candidates to be matriculated for the degree of Dr.P.H. must be persons of demonstrated ability and promise of leadership. They must normally hold a doctoral degree from an acceptable university; although in exceptional cases, candidates of unusual experience and attainment may be admitted without such a degree.

13. The candidate for the Dr.P.H. must complete—or must already have completed—basic courses equivalent to those required for the degree of M.P.H. by the university in which such student matriculates for the Dr.P.H.

14. The candidate, in addition to fulfilling criteria 12 and 13 must complete a minimum of one academic year of work in residence at the university involving advanced specialization in the particular area of public health for which the student is preparing. The total period of academic instruction in public health should be at least two years beyond that spent in acquiring previous doctoral degrees.

15. The candidate must demonstrate ability for leadership in his field, as well as for advancement of scientific knowledge. This must be indicated by successful professional experience in a post involving the exercise of substantial initiative and responsibility, preferably prior to admission.

16. The candidate must indicate capacity to make substantial contributions to the advancement of the science and art of public health by submitting a dissertation, *based on original research*, satisfactory to the authorities of the university.

Credit Lines

WEST VIRGINIA STATE DEPARTMENT OF HEALTH

"A Close-Up View" by the West Virginia State Department of Health is subtitled "A Picture of Public Service in West Virginia." It shows what can be done with a typewriter, a mimeograph machine, and a little imagination. In 9 widely spaced pages it asks and answers 19 questions about public health in West Virginia beginning with "What is public health?" and ending with "How can we get better local health services?" It answers in simple straightforward language two of the questions most frequently asked by laymen, "What is a local health department?" and "What should a local health department mean to me and my family?" For those states or communities that neither have a large printing budget nor color and drawing artists at their command, this "Close-Up View" should be useful in showing how to present basic facts for busy people. The address of the West Virginia State Health Department is Charleston 5, W. Va.

THE CHILD WITH SPECIAL HEALTH PROBLEMS

At a joint session of the American School Health Association, the School Health, and the Maternal and Child Health Sections at the 76th annual meeting of the A.P.H.A. in Boston, a panel discussion of *Children with Special Problems* was a part of the program. This is a report recently published by the National Tuberculosis Association by its Committee on Educational Adaptations for Children with Special Health Problems, whose Chairman is Charles E. Wilson, M.D., of Yale University. The full title of the report is *Children with Special Health Problems: Educational Adaptations in School, Home and Hospital.*

The report centers on tuberculosis, nutrition, rheumatic fever and heart disease, and a miscellaneous group of conditions including convalescence, diabetes, allergies, and epilepsy. The crippled, the blind, and the deaf are not considered since there is already a large body of published information on these conditions.

The purpose of this brief report is to encourage everywhere "the adaptation of education to the needs of individual children," a principle everywhere agreed upon but not yet everywhere put into practice. The key to effective adaptation of educational processes to the needs of the special child is teamwork between parent, teacher, physician, hospital, and health department. It is an excellent guide for school physicians, administrators, nurses, teachers, and health agency workers.

The report, which includes a brief set of references on each special condition discussed, is available from state and local tuberculosis associations.

ANOTHER CONSOLIDATION IN INDIANA

Some time ago Floyd and Harrison Counties of Indiana took the leap into matrimony and organized the first bi-county health department in the state. But the City of New Albany in Floyd County, with its population of about 25,000, decided to stay on the outside. Now its health officer has resigned and the city fathers "got religion." They have consolidated the New Albany Board of Health with the Floyd-Harrison County Health Department. The city will join in the county organizations program and share the

services of the joint department. There will be one vital statistics office for the two counties and the City of New Albany. Congratulations are in order for all concerned.

TAKING TIME BY THE FORELOCK

At the end of the Association's annual meeting in Boston, on November 12, advantage of the interest stirred up in health matters in the newspapers and the radio was taken to have "the greatest single lack in America's public health program—full-time, well-staffed local health units—" discussed on Radio Station WHDH, Boston.

Those taking part were Martha Eliot, M.D., Associate Director of the Children's Bureau in Washington and retiring President of the American Public Health Association; Hugh R. Leavell, M.D., Professor of Public Health Practice at the Harvard School of Public Health; and Arthur Burke, M.D., District Health Officer of the Nashoba Health District, made up of ten towns. They were introduced by Vlado A. Getting, M.D., Massachusetts Health Commissioner. New England listeners were reminded of the well known facts that thousands of communities are without the local health services that should reach every citizen and that these services can be had only by the coöperation in a unified department, of communities too small to operate with effectiveness individually.

TOXICOLOGY OF SOME INSECTICIDES

"Toxicology of the Newer Agricultural Chemicals" by Arnold J. Lehman, M.D., Chief, Division of Pharmacology, U. S. Food and Drug Administration, should be of interest to everyone using the newer insecticides. A discussion of mean lethal doses as well as toxicity by dermal application is discussed. The article appears in the *Quarterly Bulletin,* Association of Food and Drug Officials of the United States, XII:3 (July), 1948, also as a supplement to the *Service Letter,* National Pest Control Association, Inc., 3019 Fort Hamilton Parkway, Brooklyn 18, N. Y.

SURVEY OF STATE HEALTH SERVICES BY WISCONSIN MEDICAL SOCIETY

Instances multiply in which the American Medical Association or its state or county societies are providing statesmanlike leadership in increasing both the quantity and quality of official public health services. The latest such instance that has come to hand is the *Report of the Technical Committee of the Wisconsin State Medical Society* to the subcommittee on reclassification and review of administrative agencies and state services of the legislative council, made up of two state senators and three representatives.

This survey of a state's public health organization could well serve as a model for such surveys in other states. It is a reasoned, restrained document completely free of special pleading. In making recommedations, it takes full account of the difficulties, traditional and otherwise, that stand in the way of their being carried out and the efforts already begun to overcome current shortcomings.

The cost of the study and publication was borne by the State Medical Society. The technical committee making it consisted of:

Dr. Gaylord W. Anderson, Director of the School of Public Health, University of Minnesota

Dr. W. W. Bauer, Director of the Bureau of Health Education of the American Medical Association and former City Health Officer of Racine, Wis.

Dr. Carl D. Neidhold, past chairman of the Council on Scientific Work of the State Medical Society and a member of the Board of Health of the City of Appleton since 1934

Dr. H. Kent Tenney, past president of the Dane County Medical Society and advisor to the Bureau of Handicapped Children of the Department of Public Instruction

Information is not given as to whether the study is available for limited or general distribution, but the Society's address is 917 Tenney Building, Madison 3, and its Secretary is C. H. Crownhart.

KIWANIANS HEAR THE NEWS ABOUT "DRUNKS"

The speed of today's communication is graphically illustrated by "Iron Bars or Medicine?" in the *Kiwanis Magazine* of October, 1948, written by Anton Carlson, M.D., and Joseph Hirsh, President and Executive Director respectively of the Research Council on Problems of Alcohol. Its thesis is that chronic alcoholism is a disease, not a crime, and is a community problem. Medical and public health circles have only yesterday been persuaded of this thesis; in fact many are not yet persuaded. But already the organ of a great citizen group recognizes that "a wide awake and interested public can make the principles" of a medical approach to this problem "a living reality."

CITIZEN JOE WANTS HIS FACTS STRAIGHT

An interesting example of telling the citizen about health services in terms he can understand is *Major Activities* of the Connecticut State Department of Health. Done in blue and white, it tells how the state health department helps the garage where Mr. Jones works to overcome dangerous monoxide gas, how Mrs. Jones gets service in a prenatal clinic, how 5 year old Johnny was vaccinated, how the milk and water of the community were made safe. From that point it goes on to tell in conventional style the activities of each of the bureaus in the state health department.

KEEPING UP WITH THE BRITISH SOCIAL SERVICES

In November, the British Information Services (30 Rockefeller Plaza, New York 20) published No. 1 of its "Notes on British Social Services," which it expects to issue from time to time. This first issue summarizes briefly a good deal of information on the new health services and experimental industrial health service, social insurance, the disabled, as well as mentioning books for reference. This is a good way to keep up with the factual information on what is happening in the British Social Services.

COMMUNITY CARDIAC RESOURCES

The Philadelphia Heart Association has prepared a *Guide to the Use of Community Services for Heart Disease and Rheumatic Fever Patients in Philadelphia.* In an 11 page pamphlet it gives the main facts about treatment, convalescent care, home teaching, occupational therapy, social case work, vocational rehabilitation, follow-up, and recreational facilities. It further reminds the reader that rheumatic fever, as a reportable disease, should be reported to the Philadelphia Health Department as soon as the diagnosis is made.

NEW JERSEY HAS A FIRST

The report is now out of the First Annual Public Health Institute of Passaic County (June, 1948), sponsored by the Passaic County Tuberculosis and Health Association. A committee headed by Frederick P. Lee, M.D., Health Officer of Paterson, planned a two day institute in June limited to active public health workers in New Jersey. Panel discussions on Mental Health Approach to Public Health Activities, Methods and Materials in Health Education, and Communicable Diseases were held.

The report which includes a brief preface telling how arrangements were worked out is presumably available from Walter S. Page, Jr., Executive Secretary, Passaic County Tuberculosis and Health Association, Paterson 17, N. J.

BIBLIOGRAPHY OF PUBLIC HEALTH MOTION PICTURES AND FILM STRIPS

The accompanying bibliography of health film catalogs and general catalogs listing films on health subjects was prepared, at the suggestion of the Committee on Public Health Films of the Public Health Education Section of the American Public Health Association, for initial use at the Annual Meeting in Boston, November, 1948. It was assembled by Thomas C. Stowell, Assistant Director, Office of Public Health Education, New York State Department of Health, and Anne J. Edmund, Health and Welfare Division, Metropolitan Life Insurance Company, and represents materials which they have found useful in their programs.

This should not be considered a complete listing, but rather a start on something which it is believed will be helpful to public health workers in their health education activities. The Public Health Education Section has recommended that the bibliography be an annual publication in the *Journal*, with reprints for general distribution, and the committee will appreciate recommendations for future lists, which may be sent to Mr. Stowell at 18 Dove St., Albany 6, N. Y. It is proposed that future lists include the date of each catalog.

Reprints may be obtained from the Association headquarters in New York City.

General Catalogs

"Educational Film Guide"
H. W. Wilson Company, 950 University Avenue, New York 52, N. Y.

"Educators Guide to Free Films"
Educators Progress Service, Box 497, Randolph, Wis.

Agencies Having Information on Films

The National Publicity Council, 130 East 22 Street, New York 10, N. Y., maintains a collection of more than 1,000 health films exclusive of medical films for use in the elementary schools. Some of the health films are reviewed in CHANNELS.

Many national agencies sponsor films relative to their fields of interest, such as, tuberculosis, heart, cancer, social hygiene, infantile paralysis, blindness, etc.

COÖPERATION IN APPRAISING SCHOOL-CHILD HEALTH

Health Appraisal of School Children is a report of the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association. It points out that parents, teachers, nurses, and physicians all have a part to play in keeping the health of school children under continuous appraisal. It defines specifically the part for which each should be responsible.

Among the points stressed are the following: (a) the frequency of routine medical examination of school children may safely be reduced to once every three years provided parents, nurses, and teachers are alert to discover children in need of medical advice or treatment; (b) every school should have a medical adviser, but where physicians' services are not immediately available, an appraisal system conducted by teachers and nurses is much to be preferred to no system; (c) information the teacher has regarding the child should be shared with the doctor and vice versa.

Although the report has little that is really new, it is, nevertheless, important because it represents the common thinking of educators and physicians in what has for many years been a field of controversy and limited accomplishments. If local school authorities would build school health services on the sound foundations here set forth, the field of school health would shortly take its rightful place as one of the most effective parts of the public health program. The report is available from the Ameri-

can Medical Association, 535 North Dearborn Street, Chicago 10, Ill.

SOMETHING NEW OUT OF THE WEST

The Laboratory Section of the Washington State Public Health Association, a new affiliate of the A.P.H.A., has for more than a half year, been putting out a monthly *Laboratory Review*. Mimeographed, this is a brightly written three or four pages of news of interest to laboratory workers throughout the state. The editorial office is the Laboratory of Providence Hospital, Everett, Wash.

A MENTAL HEALTH PROJECT

In more and more communities the tuberculosis association is meeting the challenge of the large contributions to its work by the public through the annual Christmas Seal Sale by expanding its activities to other health problems as well as tuberculosis. One such recent instance is in Ulster County, New York. There an experimental mental health education project is planned by the county tuberculosis and health association with a subcommittee of the County Medical Society serving in an advisory capacity. The project will be opened with a series of 13 15 minute radio dramas entitled, "The Tenth Man" produced by the Mental Health Foundation.

DANNY'S DENTAL DATE

The Colorado State Department of Public Health has just released a film for elementary school dental education entitled "Danny's Dental Date." Produced under the supervision of Dr. Robert A. Downs, Director of the Public Health Dentistry Section, it is a 16 mm. sound and color film with a showing time of 21 minutes.

The first part of the film, done with puppets, shows Danny learning about the types of teeth and various kinds of foods recommended for dental health. Then a human Danny visits a dentist's office where a simple filling is being done while the steps of the process are carefully explained. This is designed to dispel the fear often associated with a visit to the dentist. A super-size tooth brush is used to demonstrate proper brushing technique.

The film is available for circulation in Colorado through the Public Health Library of the State Department of Public Health, 616 Colorado Building. Inquiries regarding the purchase of prints should be sent to the Director of Health Education, Colorado State Department of Public Health, Denver.

KNOW THYSELF—THROUGH HEALTH EXAMINATION

The Cook County (Illinois) Health Department has an exhibit poster and a leaflet entitled "Know Thyself," in encouragement of annual health examinations. "Age is not measured in years but in ability to live," it says. The leaflet has a very interesting graph giving the average life expectancy at birth in various periods of history. Each period is represented by the current mode of transportation of the age, prairie schooner for 1850, steam railroad for 1900, automobile for 1930, etc. An effective and simple piece of health education material.

INTEGRATING PREVENTION AND CURE

In May, 1947, the Maryland State Department of Health appointed a Health Officer Committee on the Coordination of Preventive and Curative Services whose major task was to determine the most effective means of improving and integrating the preventive and curative services of county health departments. The committee's recommendations are presented in an article, "Coördination of Preventive and Curative Health Services," in the June issue of the *Maryland Health Bulletin*. Considerable emphasis is directed toward improving physician and health officer

relationships. The expansion of prenatal clinics, the establishment of new consultation clinics, and the enlargement of laboratory services are among the recommendations. Consideration of the need for providing routine physical examinations for recipients of medical care is also suggested.

ATOMIC BOMBS

What You Should Know About the Atomic Bomb has been prepared by the Surgeon General, U. S. Army, giving medical officers and others involved, basic information about the medical aspects of the atomic bomb and its effects. The pamphlet succeeds in discussing this abstruse subject so that most persons with college chemistry and physics should be able to understand. It is available from the Surgeon General, U. S. Army, Washington, D. C., free of charge.

DEPARTMENT OF ESOTERIC FACTS

The 1946–1947 biennial report of the Duluth, Minnesota, Health Department lists as many incinerator operators as nurses on the department staff. It estimates the city's 1947 population to be about 100,000, one nurse and one incinerator operator per 15,000 population. We won't attempt to explain the significance of this fact except that it hit us in the eye. We won't even say this properly belongs in Credit Lines.

SET OF CANCER POSTERS

The Illinois State Health Department Division of Cancer Control (Springfield) is distributing a set of 15 exhibit size cancer information posters in attention calling colors. If they don't scare the public to death, they should be useful in getting it to pay attention to early signs of possible cancer.

MINNEAPOLIS HEALTH EDUCATION DEMONSTRATION

A demonstration of health education being carried on in two Minneapolis schools, one elementary and one junior high school, is now in its second year. Among the activities is a slumber room in the elementary school which is under the supervision of a committee of mothers who take turns being on duty. Children needing the rest are selected by classroom teachers, nurse, and doctor. Student health councils, school lunches, and safety committees are other devices. Some of the results of the first year's demonstration are summarized in *School Bulletin,* Minneapolis Public Schools, June 14, 1948.

BREADTH, DEPTH, AND LENGTH

Defining the object of geriatric medicine as adding depth and breadth to life, rather than mere length, July-August *Therapeutic Notes,* of Parke, Davis & Company (Detroit 32, Mich.), is a special geriatrics issue. Various articles describe the aging process, indicate the implications of an aging population, the medical and surgical aspects of geriatrics. Not the least valuable feature of the pamphlet is a 72 item bibliography on Geriatrics. *Therapeutic Notes* is distributed without charge to the medical profession.

WORTH ACQUIRING

Motion Pictures and Slides on Public Health—Is the newest film catalog including all the titles in the film libraries of the California State Health Department, California Tuberculosis Health Association, and the California Offices of the Metropolitan Life Insurance Company. Available on request from Bureau of Health Education, California State Health Department, 760 Market St., San Francisco 2.

Baby Book, New York State Department of Health—This attractive little booklet on baby care, pre-natal and post-natal, announces that "if it succeeds only in making you more at ease

with your baby, it will have achieved its purpose." There are suggestions for feeding, clothing, and enjoying your baby, among others. Done in good printing and pleasing pastel colors.

"Medical Care for the Individual" and "The Issue of Compulsory Health Insurance": A Review of the Report of the Brookings Institution by Michael Davis and Dewey Anderson, has been printed for the use of the Senate Committee on Labor and Welfare, at the request of Senators James E. Murray and Claude Pepper, both members of the Subcommittee on Health. Available from the U. S. Government Printing Office, Washington, D. C.

ANNUAL REPORTS

National Tuberculosis Association 1947–1948—In an attractively produced pamphlet, dedicated to Kendall Emerson, M.D., the managing director for 20 years beginning in 1928, this report is a forthright listing of the many areas of activity which this Association carries on. Throughout its pages one finds an awareness of the close relationship between general public health and tuberculosis activities. There is an awareness too of the public responsibility inherent in an agency that, with its locals, annually receives nearly $20 million from many millions of the general public. This annual report is in a sense an accounting of stewardship written so that the millions of supporters may feel a share in the program. The report recommends that:

a. Every person of 15 years or over have a chest x-ray periodically and that present inadequate x-ray facilities be increased.

b. 33,000 additional beds for tuberculosis are needed and many of the present beds should be replaced.

c. A tuberculosis control officer should be on the staff of every state and large city or county health department.

d. More local health units with qualified full-time personnel should be created.

e. Tuberculosis activities of WHO should be expanded.

The Regional Hospital Plan: The Second Year's Experience—Because the Rochester (New York) Regional Hospital Plan is one of few such plans yet in operation, the second year's experience of this one should be useful to everyone who has interest in hospital, health center, or health unit development. Council of Rochester Regional Hospitals, 133 East Ave., Rochester 4, N. Y.

Oklahoma Merit System Council Annual Report—For the third successive year Credit Lines calls your attention to this annual report as an excellent graphic illustration of the workings of a merit system. Oklahoma Merit System Council, Oklahoma City.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

Racial Variation in Immunity to Syphilis—*By C. N. Frazier and Li Hung-Chiung. Chicago: University of Chicago Press,* 1948. 122 pp. Price, $2.50.

This thoughtful monograph consists of a comparison of the manifestations of syphilis in Chinese patients of the clinic of the hospital of Peiping Union Medical College, and white and Negro patients attending the Johns Hopkins Hospital syphilis clinic. It is carefully documented, and the data are analyzed with the usual statistical tests of significance.

While this study substantiates some of the characteristics of syphilis in the Chinese which have long been accepted on inadequate evidence, such as the frequency of cutaneous and skeletal lesions of both the early and late stages, and the infrequency of general paresis, it quite discredits others, such as the rarity of tabes dorsalis and cardiovascular lesions among the Chinese.

It has long been known that later manifestations of syphilis are more mild in the female than in the male of the white and Negro races. Frazier and Li point out that, with one notable exception, the pattern of late manifestations in both sexes in the Chinese resembles that of the females of the other two races. This is correlatable, in the authors' opinion, with the anthropological evidence of the relative femininity of the Chinese male, according to western standards. This in turn is suggestive of the influence of the female sex hormone in the localization of late syphilitic lesions, rather than the protective effect of pregnancy. The exception to the feminine localization of late lesions in the Chinese was tabes dorsalis. This syndrome appeared in the Chinese with the same frequency as in the white, while the Negro was affected much less frequently than either of the other races. The authors point out that chronic dietary deficiency of the poor of Peiping, which could have led, through deficiencies in the B-complex vitamin, to degenerative lesions of the posterior columns of the spinal cord, or possibly have influenced localization of the spirochete in these tracts. No evidence was adduced to settle this point.

The monograph is recommended as deserving of careful study by those interested in syphilology and as an example of the information to be derived from thorough study of clinic records.

JAMES H. LADE

Dairy Bacteriology—*By B. W. Hammer. (3rd ed.) New York: Wiley; London: Chapman & Hall, Ltd.* 1948. 593 pp. Price, $6.00.

The 18 chapters of easily read type upon a good grade of paper carry 49 figures from photographs having a pertinent relationship to the text; 1,303 references, distributed at the close of each chapter, are representative of topics useful to the student of, or worker in, dairy products. Forty-seven useful pages to the public health officer consider "Spread of disease through milk and milk derivatives." One paragraph on milk-borne rabies with its 4 references provides the information on a question which is not infrequent in presenting itself where rabies, dogs and cattle can get together.

The reviewer experienced the unusual in having his appetite whetted during the reading of a textbook on bacteriology! 73 pages on cheese; 77 pages concerning butter; chapters on ice cream,

milk, cream, cultured milk; all written in a way that assures the reader that care in the compounding of quality ingredients accomplishes a safe and satisfying variety of food.

"Bacterial counts on milk" is a sensible presentation concerning routine and research counts. Included are fair, non-prejudiced comments for and against the plate method and the microscopic method. Differential media for detection of proteolytic, acid-forming, lipolytic or other types of organisms are of special interest in investigations on dairy products.

This book becomes an important addition to the reviewer's library pertaining to public health bacteriology. It is a readable reference rather than simply "a textbook." R. V. STONE, SR.

Report of the Sanitary Commission of Massachusetts 1850—*By Lemuel Shattuck and others. Cambridge: Harvard University Press*, 1948. 321 pp. Price, $4.50.

This historic document, "one of the most remarkable documents—perhaps the most significant single document—in the history of public health," has now been reprinted in a facsimile edition by the Harvard University Press with the coöperation of "The American Public Health Association, the Massachusetts Public Health Association, the Harvard Graduate School of Public Health, the Massachusetts Department of Public Health and the Boston Health Department."

Lemuel Shattuck—1793–1859—was a bookseller and publisher of Boston who was largely responsible among other things for the establishment of the Massachusetts system for the registration of births, deaths, and marriages. The *Report* is now republished for the first time since its original release in 1850. The foreword by Professor Winslow for this facsimile edition is a superb summary of the place which the *Report* has acquired in the century since the appointment of the Commission. The foreword and the *Report* itself should be required reading in every graduate course of public health, in North America. This volume for decades has been a highly prized collector's item, but is now available in a splendid edition for which the Harvard University Press is to be congratulated. It belongs on the shelf of every library. (See symposium on Lemuel Shattuck in this issue.) REGINALD M. ATWATER

Standard Methods for the Examination of Dairy Products—*By the American Public Health Association. (9th ed.) New York: A.P.H.A.*, 1948. 373 pp. 37 illus. Price, $4.00.

The ninth edition of this laboratory manual for standard procedures for the examination of dairy products contains many advantages over previous editions. It has additional values for the laboratory worker.

The reference and cross-reference are of real benefit in enabling the laboratory workers to refer to directions and instructions without doing a lot of unnecessary reading.

The detailed and complete index makes it easier to find what one is looking for.

The introduction of new methods such as the Resazurin procedures for determining extraneous matter in dairy products, methods for detecting pathogenic bacteria in cheese, and methods for the bacteriological examination of stabilizers are worthy contributions.

The absence of highly technical terms makes the volume more interesting to the beginner, enabling him to grasp the meaning of things more readily.

The grouping of material and suggestions useful to administrative officers in one chapter is a real contribution and a decided improvement.

The elimination of repetition in comparison of methods and standards makes

the edition superior to others, enabling the reader to follow through without the necessity of reading some parts over and over again. O. A. GHIGGOILE

A Catalogue of Certified Professional Motion Picture Films—*Presented as a Service of Academy-International of Medicine. (2nd ed.) Topeka, Kans.: Department of Audio-Visual Aids,* 1948. 110 pp.

This catalogue, the second edition, of the Academy-International of Medicine, is a valuable contribution to those within the Academy's Fellowship and the profession at large. To a limited extent it contributes to the general field of documentary films and can well be studied with a view of adaptation, under proper auspices, to a wider audience.

The Audio-Visual Service for Fellows, briefly outlined in the report, provides, free of charge, projector and accessories equipment. It also provides a list of recognized professional motion picture production technicians and laboratory assistants that may be called on for all production requirements or technical aid.

The report announces the following additional services: Electronic-Sound and Motion Pictures, (an entirely new method of producing and projecting motion pictures); Sound and Slidefilm (strip-film) service; Synchronized Sound-on-disc slidefilm projection and accessories service; Photoduplication service, and others.

The catalogue lists films under 38 groupings, beginning with Anatomy and ending with Radiodontia. For the laity (first aid and health education, dental education for school children and adults) about 225 subjects are listed.

Apparently no attempt has been made to evaluate the films, since only the subject and source are given. However, it is stated that the films listed have been approved, authorized, certified, passed or reviewed by a duly organized committee, or sponsored by a professional organization or an institution. These agencies are listed and coded for references.

Of particular interest is the report's announcement that their Audio-Visual Aid Department has completed arrangements for the establishment of a loan library of motion pictures and slidefilms for which subjects are now being selected. The public's suggestions are requested to assist in the selection of preëminent films to form the nucleus of this library.

KENNETH D. WIDDEMER

The Machinery of the Body—*By Anton J. Carlson and Victor Johnson. (3rd ed.) Chicago: University of Chicago Press,* 1948. 639 pp. Price, $4.50.

This elementary textbook of human physiology has become and continues to be a classic in its field. The new book differs from the 2nd edition (1941) in the extensive consideration of the results of wartime experience and research. This material as that of previous editions is approached in the healthy spirit of critical inquiry, entirely free from any trace of the currently popular pose of awed amazement currently, popular in dealing with the facts of elementary science. Only in a few sections of the book does the text exceed the demands of an elementary presentation, but frequent footnotes indicate advanced reading on every subject considered. The parts which have received amplification beyond the basic demands of the subject are clearly marked and may be omitted without destroying continuity of subject treatment.

The mechanisms of the human body are covered in 15 chapters, followed by a selected list of references and an index which is unusually complete for a book of this type. The exposition is clear and brief throughout, and style and typography combine to facilitate reading. The subject matter is clarified by the inclusion of over 200 illustra-

tions, most of which are of a simplicity designed to aid understanding. Even the 15 tables used fail to abet confusion in the manner usually achieved in textbooks on science.

Surveying this book as a whole, there is little that one can find to criticise. The occasional relapse into the use of slang, the evanescent idiom of the current moment, is to be regretted. Replacing the precision of conventional forms of English expression with the generalities and changing connotations of the jargon of those who know no better seems to be a doubtful aid to clarity. However, this is probably a personal opinion and in any case this excellent treatment of the basic facts of human physiology sins but slightly in this regard.

DONALD YOUNG SOLANDT

How Laymen Cut Medical Costs—*Public Health Institute. Chicago: Lakeside Press,* 1948. 35 pp.

This small book describes chronologically the remarkable growth of the Public Health Institute of Chicago, a nonprofit venereal disease clinic founded in 1919 to bring to the civilian population some of the procedures developed by the army's educational and medical campaign against venereal disease infection in the first World War. Except for a decline in services during the depression years, the clinic expanded steadily until its eventual transfer to the Medical School of Northwestern University in 1947. The description of the successful campaign waged by the Institute against the prejudice and false modesty which prevailed during the early years of its development is interesting and the results bear witness to the efficacy of health education coupled with available and affordable medical care.

The title may lead one to believe that the book deals with general medical care rather than with the control of venereal disease alone. On several occasions in the text, the accomplishments of the clinic, under voluntary auspices, in treating venereal disease are used as an argument against governmentally sponsored prepayment plans for comprehensive medical care, a conclusion which is unwarranted on the basis of the limited program offered by the Institute. The Institute itself received federal funds later in its history and was able to extend its services to many who could not pay even its low fees for the treatment of venereal disease.

The argument that the Institute points the way to a method of providing low cost comprehensive medical care is largely refuted by the refusal of the Chicago Medical Society of its offer to them to own, manage, and control the clinic, and to extend its field of operation to every disease. In fact, the eventual transfer of the Institute to the Medical School of Northwestern University resulted from the failure to establish a harmonious relationship between the organized medical profession and the clinic.

HENRY B. MAKOVER

New York City's Baby Book—*A Handbook for Parents. New York City: Department of Health,* 1947. 136 pp. Free.

New York City's Baby Book is one of the most practical "guides" for parents that has been written. It covers the first two years of the baby's growth and development. Simple words and short sentences clearly tell parents (father is included) what they want to know. Emphasis is put on the point that babies are individuals and behave as such. The authors will give parents who use the book a sense of relief from tension in the business and pleasure of raising a baby. At the same time there is abundant counsel about the baby's need for love, food, and training. The handbook has combined scientific information with common sense.

DAVID B. TREAT

Occupational Pamphlets—An Annotated Bibliography—*By Gertrude Forrester. New York: H. W. Wilson Company,* 1948. 354 pp. Price, $2.50.

Publications on occupations are coming off the press in increasing numbers. This makes it difficult for librarians, counselors, and job seekers to keep abreast of the vocational literature (mostly pamphlets) prepared by bureaus of vocational guidance, commercial publishers, professional and trade organizations, governmental agencies and others. Gertrude Forrester's *Occupational Pamphlets: An Annotated Bibliography* represents a considerably enlarged edition of her 1946 volume entitled: *Occupations: A Selected List of Pamphlets.*

The new bibliography is divided into two main parts:

1. Pamphlets published in series, arranged alphabetically according to the publisher of the series.

2. An annotated bibliography, which includes essential information on each pamphlet.

Altogether 3,000 pamphlets by 360 publishers are listed. Among them are 236 pamphlets issued by professional, trade, and national organizations. About these, the author says: "The reader may confidently rely on pamphlets prepared by professional organizations with professional codes of ethics. It would be desirable to have more from such sources. . . ." Several of the publications of the Committee on Professional Education of the American Public Health Association are included in the annotated bibliography.

In selecting the pamphlets to be included in this bibliography the author used the following "Criteria of a good occupational pamphlet": 1. authenticity; 2. objectivity; 3. recency; 4. suitability; 5. availability; 6. information not found elsewhere; 7. references to further reading; 8. style; 9. format.

The reader will also find a publishers' directory, a chapter for librarians and counselors on the filing and indexing of occupational pamphlets and suggestions on the use of the bibliography in this useful reference book.

FRANZISKA W. RACKER

Eating for Health—*By Pearl Lewis. New York: Macmillan,* 1948. 121 pp. Price, $2.25.

This book is good reading and worth keeping for reference. College students majoring in foods and nutrition and beginning medical students should find helpful the author's clear and brief explanations, the index, and the carefully selected bibliography.

While the author recognizes that "eating has become one of the main pleasures of life," she is almost too generous to the ordinary person when she states that, "we now eat to maintain health or to regain it." This reviewer doubts seriously whether many persons select food *primarily* to maintain health. However, an increasing number of individuals wish to plan meals intelligently, and this book can help such thoughtful men and women.

The chapter on "Food" is especially well organized and clearly presented. In twenty pages the author explains simply and clearly how food is used by the body, and lists food sources of the vitamins and minerals.

Miss Lewis describes particularly well the structure of the body and the function of its parts. The next chapter, "Nutritional Processes," is more difficult reading because of the necessity for using technical language. This, however, is the chapter which the college student may find most helpful.

In the chapter labeled "Dietary Plans," dietary and meal plans for each age group are outlined. Height-weight tables for children as well as for men and women are a convenient addition to the book.

The last chapter, "Foods for Good

Nutrition," considers classes of foods. Not only is the nutritive value pointed out but appropriate cookery methods, season and good storage practices are indicated.

The title of this book, "Eating for Health," is not a glamourous one nor, we fear, will it appeal to the ordinary man who reads only as he browses. Those interested in health, however, will like the title. A number of those who have been led astray by faddists will be attracted to it and will benefit along with many other people from reading this new book by Pearl Lewis.

PAULINE MURRAH

Basic Principles of Ventilation and Heating—*By Thomas Bedford. London: H. K. Lewis & Company, Ltd.,* 1948. 401 pp. Price, 25s. net.

The scope of this book is wider than might be suggested by its title. Its first nine chapters deal with the "basic principles" of the relations of the thermal environment to the health and comfort of man and its last twelve chapters with the "basic principles" of the art of air-conditioning. Dr. Bedford has an unusual familiarity with the literature and practice on both sides of the Atlantic, combined with excellent judgment and discrimination. The first part of the volume tells the engineer what he should know about the fundamental physical and physiological problems involved, while the second part tells the health expert what he needs to know about the work of the heating and ventilating engineer. The book is strongly recommended to both health officers and sanitarians as the best brief summary of this field of public health now available.

C.-E. A. WINSLOW

Health Services in England—*By R. C. Wofinden. Baltimore: Williams & Wilkins,* 1947. 186 pp. Price, $2.50.

Health Services in England was awarded a prize for ". . . the best essay on the treatment of the sick poor of this country and the preservation of the health of the poor . . ." In true British fashion neither the title nor the award gives one any indication of the scope of the book nor of the genius of the author in his treatment of the material. Dr. Wofinden has accomplished one of the most difficult feats in writing, that of compressing a mass of material without losing its vividness or its significance. The growth and development of the various health services in England come alive in this small book.

The introduction summarizes the growth of the health services in England from the 16th century to the beginning of the last war, including a number of acts dealing with social conditions as well as those concerned primarily with health. Throughout the whole book the author shows a keen appreciation of the interrelationship of social and economic conditions with health conditions. Following the introduction, the book is divided into chapters on The Treatment of the Sick, The Preservation of Health, Achievements of the Health Services, The Future, and a Postscript on the National Health Service Act of 1946.

In the space of three pages, Dr. Wofinden describes the growth of the general practitioner services, including the district medical service, and introduces philosophical points pertaining to treatment of the sick under the various schemes that have been developed since the first Poor Law Amendment Act of 1834. He points out some of the particularly successful schemes such as the one worked out in the Highlands and Islands of Scotland. He then describes the formation and development of the nursing service and calls attention to crucial problems of the present day in relation to the survival of voluntary organizations.

Under "Achievements of the Health Services," the author gives due consider-

ation to the many factors in the educational and social fields which have influenced the improvement of health of the people of England along with advancements in medicine and improvement in the health services.

"The Future," Chapter V, was written before the passage of the 1946 National Health Act and gives a good background for the reactions which the present Act has met. It also raises some nice points of philosophy regarding medical care which should interest American readers.

A postscript has been added describing briefly the provisions of the National Health Service Act of 1946. A very clear summary of its main provisions is given and there is some discussion of the controversial features. The author points out that curative and preventive medicine which for some time have been bound together in England will be separated under the new Act, and raises the question as to how close liaison is to be maintained. He mentions a few of the objections of the medical profession to the Act but as a health officer he is more concerned with the possible effect the Act will have on preventive medicine in Great Britain.

The reviewer is tempted to reproduce the whole book in the review, but as that is impossible, recommends that the book be read by all those interested in health services in England and their implications for health services everywhere. It is also recommended reading for those who take delight in a skillfully constructed piece of writing in which crucial facts have been selected and woven together with thought provoking comments. MARGARET G. ARNSTEIN

Frontier Doctor—*By Samuel J. Crumbine. Philadelphia: Dorrance,* 1948. 284 pp. Price, $3.00.

Public health as a new profession needs the authentic record of its pioneers that the traditions may be soundly based. None of our older generation has had a more colorful career than Samuel J. Crumbine, as witness the stories about his original campaigns against spitting, against the fly, and the common drinking cup. Even the *New Yorker* has chosen him to be profiled.

This combination of a dramatic career and the ability of a raconteur is rare. The story is very readable and revealing of the early days in Pennsylvania and Kansas. It is sure to fire the imagination of young people and should be on the reading shelves in high schools and colleges for recruiting purposes. Those already in public health will be grateful to Dr. Crumbine for the person he is and for the fascinating story he has told.

REGINALD M. ATWATER

The Diabetic's' Handbook—*By Anthony M. Sindoni, Jr., New York: Ronald Press,* 1948. 194 pp. Price, $3.00.

With the publication of this book, another is added to the extensive list of handbooks designed to teach the diabetic how to care for his disease and cooperate with his physician. This handbook's range of topics is equally as extensive as that of several others recently reviewed; its scope is wider than that of some other handbooks on the same subject. The presentation is unusual in its emphasis upon the prevalence of diabetes and some of its public health aspects.

In arrangement, the book follows a logical sequence. The first section, questions and answers, might serve as a survey of the substance of the whole book. Several observations on this section seem worthy of comment:

1. The emphasis on routine examinations for diabetes, in the absence of symptoms, is valuable in its implications for general control measures (p. 4).

2. From experience in testing large groups of normal individuals, we must take exception to the statement that the blood sugar of normal persons "never" rises above 80 to

120 mg. per cent, even after eating (p. 3).

3. The figure on the number of living diabetics is understandably hazy; more prevalence studies will allow a better estimate.

4. If all of us were able to concur entirely with the author's blame of "indiscreet dietary habits" for the large number of diabetics, the chances for prevention would be much more assured (p. 6). At any rate avoidance of over-eating is a good hygienic principle.

Generally speaking, this handbook lacks the compactness and brevity as well as the excellent illustrations of practical techniques that contribute to the appeal of some other manuals. However, its thorough treatment of the essential phases of diabetic self-care and its easy reference arrangement make a contribution to diabetic literature.

HUGH L. C. WILKERSON

Insect Pests—*By William Clunie Harvey (2nd ed.). London, New York: Hoeber,* 1948. 347 pp. 27 illus. Price, $5.00.

This handbook is written especially for "authorities and individuals who have the responsibility of insect pest control placed in their charge."

It is divided into two sections. In the first is described the life history, bionomics, and control of insect and other arthropodal species which cause or carry disease, or are household or economic pests. The second and larger part deals with principles and practices of disinfestation in homes, commercial establishments, ships, moving vans, furniture, etc. Specimen forms, records, and propaganda leaflets are shown in the appendix.

While of general applicability in the field of insect control, this book is designed primarily for British supervisors and operators. Thus it deals with pest problems of England, with types of English construction, English brands of insecticidal equipment and materials, and with English pest control laws and regulations.

The volume contains some inconsistencies and errors. On page 68, it is stated, relative to mosquitoes, that "in the case of some species, the habit of blood-sucking is said to be common to both males and females." Five pages later, the authors claim that "The most important characteristic of the entire mosquito family is that only the females of all species suck blood. . . ." Wherever the scientific designation of the oriental rat flea occurs in the book—even in the index—the specific name is misspelled.

The chapter on "Gaseous Fumigants" is excellent in coverage and detail. DDT and Gammexane, the latter a British product, are treated together in another chapter—but chlordane, toxaphene, and other new insecticides are not mentioned. The book is indifferently illustrated. There is an index but no bibliography.

JUSTIN M. ANDREWS

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

ADVANCE OR RETREAT FOR PRIVATE FAMILY SERVICE. Bertha Reynolds. New York: United Office and Professional Workers of America, CIO. 32 pp. Price, $.50.

ANESTHESIA—PRINCIPLES AND PRACTICE. Alice M. Hunt. New York: Putnam, 1948. 142 pp. Price, $2.60.

THE BASIS OF CHEMOTHERAPY. Thomas S. Work and Elizabeth Work. New York: Interscience, 1948. 435 pp. Price, $6.50.

BLOOD'S MAGIC FOR ALL. Public Affairs Pamphlet No. 145. Alton L. Blakeslee. New York: Public Affairs Committee, Inc. 32 pp. Price, $.20.

BLOOD CLOTTING AND ALLIED PROBLEMS. Transactions of the First Conference February 16–17, 1948. New York: Josiah Macy, Jr. Foundation, 1948. 179 pp. Price, $3.25.

THE CHILD IN HEALTH AND DISEASE. Clifford R. Grulee and R. Cannon Eley. Baltimore: Williams & Wilkins, 1948. 1006 pp. Price, $12.00.

CORNELL CONFERENCES ON THERAPY. Vol. III. Edited by Harry Gold. New York: Macmillan, 1948. 337 pp. Price, $3.50.

THE CREATIVE NURSERY CENTER. Winifred Y. Allen and Doris Campbell. New York: Family Service Association of America, 1948. 171 pp. Price, $2.75.

EXPERIMENTAL IMMUNOCHEMISTRY. Elvin A. Kabat, and Manfred M. Mayer. Springfield, Ill.: Thomas, 1948. 551 pp. Price, $8 75.

FACTORS REGULATING BLOOD PRESSURE. Transactions of the Second Conference January 8–9, 1948. New York: Josiah Macy, Jr. Foundation, 1948. 170 pp. Price, $2.75.

HOW TO LIVE LONGER. Justus J. Schifferes. New York: Dutton, 1949. 243 pp. Price, $3.00.

HYGIENE, MANUAL OF PUBLIC HEALTH. J. R. Currie and A. G. Mearns (3rd. ed.). Baltimore: Williams & Wilkins, 1948. 695 pp. Price, $9.00.

INDUSTRIAL HYGIENE AND TOXICOLOGY. Vol. I Frank A. Patty, Editor. New York: Interscience, 1948. 517 pp. Price, $10.00.

AN INTRODUCTION TO PHYSICS IN NURSING. Hessel Howard Flitter. St. Louis: Mosby, 1948. 179 pp. Price, $3.25.

IRREGULAR DISCHARGE: THE PROBLEM OF HOSPITALIZATION OF THE TUBERCULOUS. Washington, D. C.: Superintendent of Documents, U. S. Gov. Ptg. Office, 1948. 64 pp. Price, $.20.

A PROPOSED HEALTH FILM PROGRAM FOR AMERICA. Prepared by The World Today, Inc., Film Producers. New York: The World Today, 1948. 35 pp. Price, $1.00.

PSYCHIATRY FOR THE MILLIONS. Benzion Liber. New York: Frederick Fell, 1949. 297 pp. Price, $2.95.

PSYCHOSOCIAL DEVELOPMENT OF CHILDREN. Irene M. Josselyn. New York: Family Service Association of America, 1948. 134 pp. Price, $1.75.

SANITATION IN SOUTH AFRICA (Applicances Illus.) John H. Moore. Cape Town, So. Africa: Jata & Co., 1948. 425 pp. Price, 35 s.

TEXTBOOK OF ATTENDANT OR PRACTICAL NURSING. Katherine Shepard (3rd ed.). New York: Macmillan, 1948. 386 pp. Price, $4.25.

Public Health in Foreign Periodicals

GEORGE ROSEN, M.D., PH.D.

MAN requires food to maintain life, but food is not easily obtained. For the great majority of the world's population the Biblical injunction, "In the sweat of thy face shalt thou eat bread," is still true. When crops fail or war breaks out this precarious situation is easily upset, resulting in malnutrition, famine, and disease. The recent war necessarily turned the attention of lay and medical groups to problems of food and nutrition. Numerous publications in the medical and public health literature attest this interest.

DIET OF NORWEGIAN FAMILIES DURING 1942–1945 [1]

From 1942 to 1945 Axel Strøm investigated the diets of families connected with two industrial concerns in Oslo (Electric Bureau and Freia) as well as several families in Arendal and Hisøy. At the Electric Bureau, five different series were studied from January, 1943, to May, 1945. At Freia there were three investigations from December, 1942, to May, 1944, and during November-December, 1943, one investigation was carried out in Arendal and Hisøy. A total of 102 families participated in these studies. For the most part these families were small and had few children. In Arendal and Hisøy two orphanages were also included in the investigation.

Each investigation period lasted 14 days. During this period a daily account was kept of the food purchased and received, as well as of the food taken out of the house. The food supply was weighed at the beginning and at the end of each period. Cathcart and Murray's scale was used for computation. Atwater's figures, 4-9-4, were used in calculating the caloric intake. Two per cent was allowed for waste in housekeeping, except in the orphanages where wastage was fixed at 10 per cent.

By comparison with pre-war conditions, the diets of the investigated families were characterized by a marked decrease in the consumption of meat, whole milk, cream, cheese, eggs, margarine (but not butter), fruit, berries, sugar, and coffee. An increase was noted in the consumption of skimmed milk, though this was not enough to compensate for the drop in the consumption of whole milk. Cereal consumption was somewhat increased, while that of potatoes, fresh vegetables, and fish was considerably greater.

In the various investigation series the mean caloric values of the diets were found to be 3,046, 3,206, 2,913, 2,905, 2,900, 2,750, 2,708, 2,708, 2,603, and 2,565 calories. The total average was 2,849 calories. Except for the first two series, all these figures are lower than those for self-supporting Norwegian families before the war.

The protein content of the diets varied between 82 and 109 gm., with an average of 93 gm. The fat content varied from 61 to 82 gm. and averaged 71 gm. The range of variation for carbohydrates was from 372 to 482 gm. with a mean of 429 gm. In comparison with previous Norwegian studies, the intake of fats was low, while that of protein and carbohydrates was satisfactory. The low caloric content of the diets already noted was attributed essentially to an inadequate fat intake.

In the various series the gross daily calcium content ranged from 1.12 gm.

to 1.53 gm. per man value, with an average of 1.32 gm. for the total series. The mean intake of phosphorus in all the investigation series was 1.95 gm. per man value per day, and varied between 1.74 and 2.22 gm. The iron content varied from 12.90 to 16.28 mg., with a mean of 14.46 mg. These values are regarded as satisfactory for calcium and phosphorus, but too low for the intake of iron.

The gross vitamin intake per man value per day was:

Vitamin A: average, 4,911 I.U.; lowest, 2,011 I.U., highest 10,029 I.U.

Vitamin B: average, 720 I.U.; lowest 616 I.U.; highest, 848 I.U.

Vitamin C: average, 98 mg.; lowest, 40 mg.; highest, 193 mg.

Vitamin D: average 1,107 I.U.; lowest, 525 I.U.; highest, 1,879 I.U.

The author considers the average vitamin consumption satisfactory, but points out the vitamin intake differed widely with various families, and it is more than likely that some families had less than the requisite amount. This applies particularly to vitamin A.

Strøm is aware that the number of families involved in these studies was small, yet he feels that the findings give a rather good picture of the diet of families in Oslo during the war. Loss of weight was frequent, but clearly defined deficiency diseases were rare. There was, however, a certain tendency to anemia, and a mild degree of night blindness prevailed.

THERESIENSTADT ANEMIA [2]

More drastic effects of malnutrition appeared among concentration camp inmates. Pick and Salus describe an unusual kind of anemia observed in the Theresienstadt concentration camp. Chronic malnutrition prevailed in the camp and the authors regard chronic protein deficiency as the most important factor in the causation of this anemia. The condition developed spontaneously or following other types of anemia. In contrast to other deficiency anemias, such as hypochromic anemia due to lack of iron or hyperchromic anemia due to deficiency of the antianemic factor, the Theresienstadt anemia was characterized by orthochromia. The authors suggest protein deficiency anemia as the most suitable name for the condition.

NUTRITIONAL VALUE OF BARK [3]

In time of famine desperate people turn to unusual sources of nourishment. The practice of eating bark bread, that is, bread mixed with the bark of Coniferae, has prevailed in the more remote northern areas of Finland for hundreds of years. During the famines of 1695–1697 and 1867–1868, hunger edema was reported to be widely prevalent in southern Finland, but was apparently absent in the north of the country. Similarly during 1918, hunger edema was common throughout Finland except in those northern areas where bark bread was eaten. From this evidence Adlercreutz infers that the bark of Coniferae may be of nutritional value and suggests further study.

DIET AND DISEASE IN THE SUBARCTIC [4]

A provocative note on the relation between diet and disease is furnished by A. C. Duncan who has spent 14 years providing medical care for the 1,500 to 2,000 people who make up the population of Dawson City, Yukon, and the surrounding area. As this population is practically isolated, it has been virtually impossible to obtain medical attention from some other professional source.

Although the population contains some 350 children under the age of 14, Duncan states that he has not seen any cases of acute rheumatic fever. Similarly, he claims not to have seen nephritis in any of its stages. Yet he reports a normal incidence of acute tonsillitis and upper respiratory infec-

tions. Duncan feels that these observations are in some way related to the diet commonly consumed by the residents. The character of the diet is determined by the geographical situation of the area. Foodstuffs such as sugar and cereals that must be transported over considerable distances are expensive and not easily available. On the other hand, meat (caribou, moose, rabbit), and fish can be obtained locally in almost unlimited amounts. As a result the diet of the inhabitants contains a large amount of animal protein.

While one may be sceptical of the author's attempt to link diet and disease, the facts which he reports—the absence of rheumatic fever and nephritis in this population—certainly merit attention.

THE HYGIENE OF MILK IN FRANCE

In certain European countries, which in the past have tended to overlook the problems of food sanitation, the present food shortage has led to a recognition that these questions require urgent attention. In France the hygiene of milk has recently been a focus of critical discussion. Thieulin[5] has given a general analysis of the problem, pointing out that its solution depends on a variety of social, economic, and technical factors. Thus the public must be educated to demand milk produced under hygienic conditions and of good quality, and the producer must be given a premium for quality production. At the same time, the consumer must also be prepared for the possibility of a resulting price increase. More specifically the problems of bovine tuberculosis and streptococcal mastitis must be solved. For this a sanitary inspection system is needed.

Guittonneau[6] points out that some improvement had already set in prior to World War II. A government decree of April 26, 1939, had incorporated demands raised at the Hygiene Congress of 1937. These included registration of the temperature of pasteurization, absence of pathogenic organisms, a maximum of 100,000 organisms per ml. of liquid milk, and that milk be sold only in sealed bottles. The war and the German occupation reversed this trend and led to a deterioration of such supervision as had existed. As soon as liberation was a reality, steps were taken to remedy the unhygienic and inferior quality of the French milk industry. In this connection Guittonneau insists on the employment of the phosphatase test, testing for *B. coli,* and a count of the total number of organisms. Of equal importance is the problem of seeing that bottles are disinfected and the milk adequately refrigerated.

J. Verge[7] presents some interesting data on the presence of tubercle bacilli in milk and milk products. He states that in France human tuberculosis of bovine origin is rare. Thus, among 1,726 cases of tuberculosis 94.9 per cent were of human type, 3.24 per cent were bovine, and 1.85 per cent were of indeterminate type. Nevertheless, because the tubercle bacilli are eliminated in transitory fashion, it is absolutely necessary that the milk be pasteurized and barns and stables supervised. In this connection Verge reports on the testing of milk from human and bovine tuberculous sources. Among female patients the milk of 10–12 per cent was found infected, and in cows 7.78 per cent. Tubercle bacilli have also been found in cream, butter, and cheese, although not in dried milk. It has been observed that the bacilli can effectively resist temperatures of 60°–63° in the manufacture of condensed milk. Verge emphasizes the obvious need for strict enforcement of pasteurization and sanitary inspection.

THE PROBLEM OF BREAD IN BRAZIL[8]

Though Brazil did grow wheat in the past, cultivation of this grain does not

occupy an important place in Brazilian agriculture at present. Because of the international trade situation not much wheat is imported. At the same time large numbers of the Brazilian people, according to Da Silva Mello, live in a state of chronic malnutrition. For this reason he has devoted himself to the problem of producing a bread of superior quality utilizing materials grown in Brazil.

Bread making experiments have been carried on by Mello, using wheat mixed with rice, maize, or manhioca flour. Recognizing the value of skimmed milk, bread has been made with 15 per cent rice flour added to wheat, and skimmed milk substituted for water. The result has been bread of fine quality. Brazilians, however, are not accustomed to the flavor of such a bread. Bread baking experiments have also been made with other flours, for example, from Cajú-chestnuts, Pará chestnuts, and soya beans. Nevertheless, the problem of providing a good nutritious bread which is not too expensive has not been solved.

De Cunto[9] discusses the nutritional significance of the soya bean, pointing out that it is a product of national importance in Brazil. Its nutritive value is due in considerable measure not alone to its protein content but rather to its glycine content. It has been shown that by mixing 10 per cent soya flour with corn, a tasty bread of higher nutritive quality can be obtained. This flour mixture (in a 50 per cent proportion) has also been used for biscuits with favorable results.

FOOD AND NUTRITION IN VENEZUELA[10]

Early in 1948 Velez Boza published an interesting and comprehensive study on the nutrition of the Venezuelan people. The subject is considered from a variety of viewpoints: historical, statistical, clinical, and biochemical. Boza deals with food production in the country and gives a classification of native and imported vegetables that are of value as food resources. There is also a complete compilation of all the Venezuelan laws from 1589 to 1945 that have been concerned with food and nutrition. Boza calls attention to the fact that the nutritional problems of the Venezuelan population vary considerably depending on the geographic area, whether it is the coastal zone or the Andean region. In all areas, however, there is need for guidance and education in nutrition. Furthermore, there is urgent need in Venezuela for the improvement of food technology, and for the provision of adequate transportation facilities. At the same time the government must provide the necessary credits for agriculturists to expand their activities.

BREAD IN CHILE[11]

The problem of bread is a matter of concern also in Chile. At its annual meeting in November, 1946, the Nutrition Society of Chile urged the need for a policy aimed at improving the quality of bread. Recognizing that improvement of bread must start with improvement of the grain from which it is made, the society called upon the Ministry of Agriculture to see that only the best varieties are cultivated. At the same time the milling industry was urged to carry on research in order to improve methods of extraction and flour production. The society likewise recommended a program of bread enrichment with vitamins. As in Venezuela, considerable attention is paid to the problem of distribution and price regulation. Finally, the society concluded that the sanitary conditions of the bread baking industry left much to be desired, and that the social condition of the workers in the industry was lamentable. Action by government, industry, and the unions was urged to remedy these conditions.

PELLAGRA IN RUMANIA

Pellagra remains one of the most serious social diseases in Rumania.[12] It was first mentioned in Rumania by Vârnav in 1836, and later by Caillat (1847), Theodori (1858), and Felix (1859). Nitzulescu points out that official figures do not give a complete picture of the prevalence of the disease. In 1945, according to the official figures, 10,302 cases were reported, but there were probably two to three times as many. He urges the need for better and more complete statistical information.

Nitzulescu also points out that the control of pellagra requires action along two fronts, one, social, and two, scientific. Social action is necessary for prophylaxis and therapy of the problems created by the poor nutrition of the peasants. In this part of the program an intensive health education campaign with emphasis on nutrition is an absolute necessity. The scientific side of the program should be based on research centers which would deal specifically with rural nutrition and its problems. These would contain sections for social, clinical, and biochemical research.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

"It looks as if the Federal Government Will Go Ahead"—An illuminating summary of "The Nation's Health" appears, of all places, in the British Medical Journal. With it is an editorial which views, with cool objectivity, our multi-million dollar scramble to block that "communistic" threat to our American institutions. The heading above is a quotation from the summary.

ANON. Medicine in the U. S. A. Report to Mr. Truman. Brit. M. J. 4584:869 (Nov. 13), 1948.

Lifeblood, She Calls It—Webster says that to evaluate is to ascertain the value (worth) of; to appraise (to judge as to quality and productiveness). Doesn't evaluation imply the use of more nearly exact measurements than is suggested by the phrase, critical examination? If we could just get a critical examination of our health educational ways and means, we'd be moving ahead. How one provincial health department does it is the burden of this useful paper.

BEARD, K. Evaluation of Health Education

Materials. Canad. Pub. Health J. 39, 11:440 (Nov.), 1948.

A Fighter Who Hated To Fight—It will do your heart good, even if it doesn't add a nickel to your market value, to read this warm but unpretentious story of one of the pioneering bacteriologists, a story lovingly put together by his son.

CONN, H. J. Professor Herbert William Conn and the Founding of the Society. Bact. Reviews 12, 4:275 (Dec.), 1948.

Amebiasis in Archangel—As a concept, tropical medicine has changed from a group of peculiar diseases to an appreciation that it is just general medicine localized.

GORDON, J. E., and AUGUSTINE, D. J. Tropical Environment and Communicable Disease. Am. J. M. Sc. 216, 3:343 (Sept.), 1948.

Rough on Rats' Fleas—If we won't get rid of rats, we can at least deprive them of most of their fleas (with DDT) and thus lessen the chance of human typhus infections. This paper tells how to do it.

HILL, E. L., and MORLAN, H. B. Evaluation of County-Wide DDT Dusting Operations in Murine Typhus Control. Pub. Health Rep. 63, 51:1635 (Dec. 17), 1948.

Institute—"Arizona is a Wonderful State!" It says so, right here, at the beginning of this paper which gives you excerpts from the script of "Molly Gets Well," a skit that entertained while it informed audiences about the care of tuberculosis. Movies, lectures and demonstrations also were used as visual aids at this institute.

HORKAVI, H. Dramatics in Health Education. Pub. Health Nurs. 40, 12:597 (Dec.), 1948.

Industrial Health Is Public Health—Local health departments have participated less in industrial hygiene than in other phases of health administration. What the local health officials' responsibilities are in this highly important field is set forth in all too meager detail.

JONES, J. L., and FARNER, L. M. Coordination of Industrial Hygiene With the General Health Field. Canad. Pub. Health J. 39, 11:433 (Nov.), 1948.

Round and Round It Goes—Four of these dozen papers have to do with the public health aspects of the control of dental caries. The others are of the "What causes that?" variety. If you are at all interested in this public health problem of the first magnitude, then you will look up the four. You'll discover no easy panaceas.

KESEL, R., *et al.* Symposium on Dental Caries by the AAAS Subsection on Dentistry. J. Am. Dent. A. 37, 4:381 (Oct.), 1948.

That $32,000 Smile—There is no secret to saving teeth. It is as simple as A B C. These are the writer's very words. The rub, of course, is putting the A B C's into administrative practice—that, and productive dental health education. Please read!

LEVINSON, C. A. The Dentistry of Tomorrow. Pub. Health Nurs. 40, 12:610 (Dec.), 1948.

Feeling Creatures—This highly successful effort to point out areas of emotional friction that "inhibit fruitful patient-nurse relationships" will be good for you whether or not you append an R. N. to your name. Never forget the *person* at the receiving end of the needle or the feeding-formula bottle, this psychiatrist urges; and his good advice applies to whatever substitute for the needle or the bottle you hold in your work-a-day hands.

MANN, J. Human Relations in Public Health Nursing. Pub. Health Nurs. 40, 12:583 (Dec.), 1948.

To Be Read for the Fun of It—Much of this debate on the motion "that the practice of instructing the layman in the nature and treatment of disease is being carried to excess," I

found provocative and about as supportive of one's pet convictions as are most debates. It was asserted that in the two countries given to excesses of health education (one of them the U. S. A.), there the quacks and nostrum vendors flourish as the green bay tree. A vote at the close gave a tiny majority against the motion.

O'DONOVAN, W. J., *et al.* Should a Doctor Tell? Brit. M. J. 4586:952 (Nov. 27), 1948.

Difficult Matters of Judgment—English writers put things so felicitously! This nutritionist concludes: at the lowest level we must accept "carrots for beauty," at the second level we must tolerate "body builders, energizers and protectors," at the level of the thoughtful citizen—one who can grapple with rational explanations—lasting progress is slowly being achieved. Nice, isn't it?

PYKE, M. Visual Aids to Nutrition Education for the Public. Nutrition Rev. 6, 12:353 (Dec.), 1948.

The Mothers Like It, He Says—Another of those timetables of immunizations. This one sharpens the needle for the infant victim once each month during the first ten, then a half dozen more jabs are given between ages one to six while the child is still unable to fight back.

SAKO, W. Practical and Immunologic Aspects of Pediatric Immunizations. Pediatrics 2, 6:722 (Dec.), 1948.

About Studying Work Distribution—Work simplification means taking the "WORK" out of work. It doesn't mean speed-up. This discussion, for the benefit of the girls who manage institutional diet kitchens, has a lot in it for women or men who manage laboratories, inspection forces, statistical record rooms and other public health administrative services. Open memo to editorial board: how about having experts from other fields than ours give us some how-to-do-it hints, like this one.

SCHMID, M. D. Work Simplification—Making the Job Easier. J. Am. Dietet. A. 24, 12: 1062 (Dec.), 1948.

Respectfully Called to Your Attention—Among all the other shortages in the nursing profession there continues to be a shortage of qualified teachers and supervisors. That bogey, which the viewers-with-alarm conjure up, the over-educated nurse, is likely to remain a figment of their agitated imaginations for many moons to come, so this reporter alleges—because many of the existing schools haven't the ability to over-educate her.

VREELAND, E. M. Some Qualitative and Quantitative Factors in Nursing Education. Pub. Health Rep. 63, 52:1667 (Dec. 24), 1948.

"Country-Cousin Attention"—There is no organized instruction in preventive medicine in twenty-eight medical schools and most of these do not consider such emphasis as important. A portrait of the medical school of the future is painted.

WEINERMAN, E. R. Medical Schools and the Quality of Medical Care. New England J. Med. 239, 22:810 (Nov. 25), 1948.

ASSOCIATION NEWS

REVISION OF THE REPORT ON COMMUNICABLE DISEASE CONTROL UNDER WAY

Preceding the 76th Annual Meeting of the Association in Boston, the subcommittee on Control of Communicable Diseases met for two days to agree upon changes for the 7th edition of the manual *Control of Communicable Diseases;* scheduled for reissue in 1950.

The committee of 14 members is headed by Haven Emerson, M.D., who has been its chairman for the third of a century since its creation in 1916. The committee has the collaboration of several national and international professional organizations and of the British Ministry of Health. The latter was represented at the Boston meeting by Dr. A. H. Gale, Medical Officer, British Ministry of Health and Dr. J. R. Peters, Chief Medical Deputy Officer, Department of Health for Scotland. WHO was represented by Dr. Frank A. Calderone, Director of the New York Headquarters Office; the Pan American Sanitary Bureau by its Director, Dr. Fred L. Soper; the U. S. Department of National Defense by Dr. Joseph E. Smadell, Director of the Army Medical Laboratory, Washington, D. C.; the American Academy of Pediatrics by Dr. Archibald L. Hoyne, Medical Superintendent of the Chicago Contagious Disease Hospital.

The members of the committee preparing the 7th edition are:

Gaylord W. Anderson, M.D., Director, University of Minnesota School of Public Health
J. A. Bell, M.D., Senior Surgeon, U. S. Public Health Service
Donald T. Fraser, M.D., Professor of Hygiene and Preventive Medicine, University of Toronto
Alexander A. Gilliam, M.D., Director, Epidemiology Division, National Cancer Institute
John E. Gordon, M.D., Department of Epidemiology, Harvard School of Public Health
William M. Hammon, M.D., Professor of Epidemiology, University of California
J. P. Leake, M.D.
Kenneth F. Maxcy, M.D., Professor of Epidemiology, Johns Hopkins University
Ralph S. Muckenfuss, M.D., Assistant Commissioner, New York City Department of Health
Alton S. Pope, M.D., Deputy Commissioner, Massachusetts Department of Public Health
Ernest L. Stebbins, M.D., Director, Johns Hopkins University School of Hygiene and Public Health
Franklin H. Top, M.D., Director, Herman Kiefer Hospital, Detroit
Norman H. Topping, M.D., Associate Director, National Institutes of Health

Meeting at the same time was the study group on Hemolytic Streptococcal Infections of the Committee on Evaluation of Administrative Practices, whose secretary is Dr. Top. Other members are Drs. Anderson, Fraser, John R. Paul, Professor of Preventive Medicine, Yale University; and Milton V. Veldee, Chief, Biologics Control Laboratory, National Institutes of Health.

In addition, the following consultants attended the group meeting:

Morton Hamburger, M.D., University of Cincinnati Medical School
T. Duckett Jones, M.D., Director of the Helen Hay Whitney Foundation, New York
David D. Rutstein, M.D., Professor of Preventive Medicine, Harvard University
Francis F. Schwentker, M.D., Pediatrician in Chief, Johns Hopkins Hospital
Homer F. Swift, M.D., Hospital of the Rockefeller Institute for Medical Research

This group made recommendations for revision of the chapters of the communicable disease control report on Hemolytic Streptococcal Infections, Respiratory and Non-Respiratory, and Rheumatic Fever. The revised chapters

were accepted by the Subcommittee on Control of Communicable Diseases for inclusion in the 7th edition.

In the new edition, control measures will be presented under four main classifications: preventive measures, those applicable to the individual case and contacts, epidemic measures, and international measures.

Treatment will not be dealt with except as it affects the period of communicability of a particular disease. A number of definitions will be added. The sections on the rickettsias and the jaundices have been materially changed due to recent new knowledge. Enterobiasis, histoplasmosis, and toxoplasmosis are among the diseases that have not been included in previous editions of this report.

The manual *Control of Communicable Diseases* was first published in 1917. The 6th edition, printed in 1945, was prepared with the agreement of the British Ministry of Health as to certain diseases, was adopted as official by the U. S. Public Health Service, the U. S. Navy, and the Territory of Hawaii, was recommended for adoption as an official statement by the National Health Administration of China, was approved for distribution to the staff of UNRRA, and was published under the imprint of 10 state health departments, and Washington, D. C., the Quebec Ministry of Health, U. S. Indian Service and the Office of War Information, the departments of public health of the Louisiana State and Yale Universities Schools of Medicine, and the Atlantic Seaboard and Northwest Divisions of the Agricultural Worker's Association. It was translated into at least 6 languages. The Pan American Sanitary Bureau was responsible for the translation and distribution of the Spanish text.

SPECIAL NOTICE TO MILK CONTROL LABORATORIES

The Sanders-Sager Phosphatase Test for Pasteurization

The Sanders-Sager Method for the determination of residual phosphatase in a wide variety of heat-treated dairy products, including milk and cream, has been adopted by the Association of Official Agricultural Chemists, *Journal A.O.A.C.*, 31:82–91, 1948. This action has created an inconsistency with respect to phosphatase methods recognized by the American Public Health Association.

The New York State Department of Health Method and the New York City Department of Health Laboratory Method I have been recognized in *Standard Methods for the Examination of Dairy Products, Ninth Edition*, for use on milk, cream, frozen desserts, chocolate milk, and butter. In the same publication the Sanders-Sager Method was adopted for use on hard type (cheddar) cheese only.

Plans are now being made for public health laboratories to join in collaborative work under the direction of the Associate Referee on Phosphatase Methods in the Association of Official Agricultural Chemists. The intent is to compare the methods as customarily used in the collaborator's laboratory on fluid milk and cream with the Sanders-Sager procedure, hoping thereby to be able to reconcile the present inconsistent status of recognition.

Copies of the Sanders-Sager Method, including the formal action taken thereon, can be obtained from the office of the American Public Health Association. These are distributed with the approval of the Joint Editorial Board, Ninth Edition, Standard Methods for the Examination of Dairy Products.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Joffre A. Diaz-Guzman, M.D., M.P.H., Avenida Orinoco, Quinta Trinamar, Caracas, Venezuela, S. A., Student, School of Public Health, Univ. of Michigan

Jose L. Garcia G., M.D., M.P.H., Unidad Sanitaria y Asistencial, Juarez, Chih., Mexico, Chief

Francisco T. Hernando, M.D., Santa Cruz, Laguna, Philippines, District Health Officer

Roy B. Jenkins, M.D., D.P.H., William Head, RR 1, Victoria, B. C., Canada, Quarantine Officer, William Head Quarantine Station

Clifford H. Jope, M.D., 1709 Dunster Road, Fort Devens, Mass., Student, Harvard School of Public Health

Laboratory Section

Velma L. Chandler, Ph.D., 535 N. Dearborn St., Chicago 10, Ill., Bacteriologic Associate, *American Medical Assn.*

Oliver D. Grace, D.V.M., 805 W. Penn Ave., Urbana, Ill., Veterinarian, U. S. Food and Drug Administration

J. *Iturriza, Edificio Atlas, Pte. Republica,* Caracas, Venezuela, S. A., Director, Laboratorio Analitico Industrial

Beatrice L. Kern, 4756 S. Drexel Blvd., Chicago, Ill., Bacteriologist, State Dept. of Public Health

Ray W. Moehring, 2224 Lawndale, Rockford, Ill., Bacteriologist-Serologist, Rockford Health Dept.

Edward P. Offutt, Jr., Ph.D., Dept. of Bacteriology, 260 Crittenden Blvd., Rochester 7, N. Y., Asst. Professor of Bacteriology and *Parasitology, Univ.* of Rochester; Director of Laboratories, Rochester Health Bureau

M. Pearl Spanswick, M.S., State Hygienic Laboratory, Iowa City, Iowa, Principal *Serologist*

Irwin J. Wachtel, Ph.G., P. O. Box 527, Red Bank, N. J., Pharmacist and Curator, "Serving Science"

Statistics Section

William Grodowitz, 601 Park Road, N.W., Washington 10, D. C., Social Science *Analyst, National Office of Vital Statistics,* U. S. Public Health Service

Karen Gunstad, 240 South 4th St., Minneapolis, Minn., Medical Records Librarian and Statistician, Out-Patient Dept., Glen Lake Sanatorium

Stanley G. Hanks, M.S., 2740 Prince St., Berkeley 5, Calif., Senior Public Health Analyst, State Dept. of Public Health

Mildred E. Harter, 813 East Ann, Ann Arbor, Mich., Resident Lecturer, Dept. of Epidemiology, School of Public Health, Univ. of Michigan

Helen L. Johnson, 501 Keech Ave., Ann Arbor, Mich., Teaching Asst., Dept. of Epidemiology, School of Public Health, Univ. of Michigan

Ann S. Kelly, R.R.L., Medical Record Librarian, Veterans Hosp., Bedford, Mass.

Nona-Murray Lucke, 1701–16th St., N.W., Washington, D. C., Asst. Administrator, Committee on Veterans Medical Problems, National Research Council

Mortimer Spiegelman, M.B.A., 90 Riverside Drive, New York, N. Y., Asst. Statistician, Metropolitan Life Insurance Co.

Everett L. Welker, Ph.D., 535 N. Dearborn St., Chicago 10, Ill., Assoc. in Mathematics, Bureau of Medical Economic Research, American Medical Assn.

Engineering Section

Joseph S. Ameen, 901 Boulevard Circle N.E., Atlanta, Ga., District Public Health Engineer, Fulton County Health Dept.

Frank H. Barr, M.S.P.H., Durham City-County Health Dept., Durham, N. C., Senior Sanitarian

Francis H. Bulot, 411 West 5th St., Los Angeles, Calif., Consulting Engineer

M. B. Crabill, Box 108, Ralston, Neb., Public Health Engineer, Omaha Health Dept.

Earl L. Fillmore, Rt. No. 7, Boise, Idaho, Sanitarian, State Dept. of Public Health

Keith A. Harvey, Box 572, Twin Falls, Idaho, Sanitarian, South Central District Health Unit

Thomas B. Henry, 821 Security Bldg., Toledo 4, Ohio, Proprietor, Jones and Henry Consulting Engineers

Major Edward E. Morrill, Jr., School of Aviation Medicine, U.S.A.F., Randolph Field, Tex.

Renato P. Pavanello, M.P.H., Via Crescenzio 58, Rome, Italy, Sanitary Engineer for Malaria Control, Commission of Hygiene and Sanitation

George E. Powers, M.S., 324 North Ave. East, Cranford, N. J., Supt., Union County Mosquito Extermination Commission

Leo H. Rothe, Court House, Corunna, Mich., Sanitary Engineer, Shiawassee County Health Dept.

Arvo A. Solander, M.S., 189 High St., Holyoke, Mass., Sanitary Engineer, Tighe and Bond

George F. Sultan, 2203 South Fremont Ave., Alhambra, Calif., Sanitation Inspector, Los Angeles City Health Dept.

Lt. Stanley J. Weidenkopf, M.S.C., 629–5th St., S.E., Minneapolis, Minn., Student, School of Public Health, Univ. of Michigan

Industrial Hygiene Section

M. J. Cuen, M.D., Medical School, Univ. of Texas, Galveston, Tex., Instructor, Dept. of Preventive Medicine

Food and Nutrition Section

Robert W. Metzger, D.V.M., R.D. No. 1, Constantia, N. Y., Division Veterinarian, Dairymen's League Cooperative Assn.

Maternal and Child Health Section

Salo M. Boltuch, M.D., 271 Central Park West, New York 24, N. Y., Practicing Physician and Surgeon

Elizabeth C. Corkey, M.D., 409 S. Pineview Ave., Goldsboro, N. C., Asst. Health Officer, Wayne and Green Counties

Mary M. Gilliland, 347 Don Gaspar Ave., Santa Fe, N. M., Administrative Asst., State Dept. of Public Health

Barbara B. Hodges, M.A., 1605 Homestead St., Baltimore 18, Md., Asst. Professor, Maternal and Child Health Division, Johns Hopkins School of Hygiene and Public Health

Ruth B. Howard, M.D., State Dept. of Health, Denver, Colo., Director of Maternal and Child Health

Erkki Leppo, M.D., M.P.H., World Health Organization, Geneva, Switzerland, Medical Officer, Maternal and Child Health Section

John G. Lynn, IV, M.D., P. O. Box 18, Honolulu 10, Hawaii, Chief, Bureau of Mental Hygiene, Dept. of Health

Robert G. Rice, M.D., C.M., 55 Shattuck St., Boston, Mass., Student, Harvard School of Public Health

Public Health Education Section

Elizabeth A. Beavers, 619 N. Van Buren, San Angelo, Tex., Exec. Secy., Tom Green County Unit, American Cancer Society

Franklin K. Brough, 281 North 2nd East, Logan, Utah, Graduate Asst., Dept. of Bacteriology, Utah State Agricultural College

Betty B. Brown, M.A., Miller County Court House, Texarkana, Ark., Exec. Secy., Cancer Information Center, Bowie-Miller Counties Medical Society

Mary K. Carmack, M.P.H., Will County Health Dept., 21 E. Vanburen, Joliet, Ill., Public Health Educator

James W. Cowden, 314–14th St., Denver 2, Colo., Exec. Secy., Denver Public Health Council

Belle Crichton, M.P.H., 117 Tuttle Rd., San Antonio, Tex., Health Educator, San Antonio Dept. of Health

T. R. Dappen, M.A., 4837 St. Paul, Lincoln, Neb., Asst. Director of Health Education, State Health Dept.

Edward Dunlop, P. O. Box 37, Ottawa, Ont., Canada, Exec. Secy., Canadian Arthritis and Rheumatism Society

Charles A. Gates, A.M., 500 Commonwealth Ave., Boston 15, Mass., Exec. Director, New England Heart Assn.

Iva L. Hartman, R.N., Pinehurst Sanatorium, Janesville, Wis., Supt.

Mary M. Karpiak, M.A., Apt. 5A, 235 Ft. Washington Ave., New York 32, N. Y., Student, School of Public Health, Columbia Univ.

B. N. Kolekar, M.B., D.P.H., Deputy Director of Public Health, Gwalior, C. I., India

W. T. Mason, 2539 Corprew Ave., Norfolk 2, Va., Supt., Norfolk Community Hospital

Elmer F. Nester, 4908 Delmar Blvd., St. Louis, Mo., Exec. Director, Group Hospital Service

Kenneth C. Ross, M.P.H., 426 Pennsylvania Ave., San Diego 3, Calif., Health Educator, San Diego County Tuberculosis and Health Assn.

A. Bernard Stein, M.A., 228 Village Lane, Boise, Idaho, Director of Public Information, Idaho Anti-Tuberculosis Assn.

Elizabeth V. Vickers, R.N., 132 East 45th St., New York, N. Y., Director, Central Club for Nurses, Y.W.C.A.

Janice R. Westaby, R.N., Box 845, La Grande, Ore., Staff Public Health Nurse, Union County Health Dept.

Public Health Nursing Section

Esther B. Bartlett, R.N., Box 214, Wayne, Ohio, Director of Nurses, Wood and Sandusky Counties

Amelia C. Beauregard, R.N., 315 Maple St., Holyoke, Mass., Exec. Director, Holyoke Visiting Nurse Assn.

Vega R. Clark, Box 845, La Grande, Ore., Staff Public Health Nurse, Union County Health Dept.

Velma P. Haley, 187 Middle St., Portland, Me., Director, District Nursing Assn.

Eugenie D. Martenson, R.N., 584 Centre St., Jamaica Plain, Mass., Public Health Nursing Coördinator, Boston College School of Nursing

Margaret W. Robertson, M.A., Royce Hall 8A, U.C.L.A., 405 Hilgard Ave., Los Angeles, 24, Calif., Asst. Professor of Public Health Nursing, Univ. of California at Los Angeles

Margaret Schnall, R.N., *1555 Odell St., New* York 62, N. Y., Student, New York Univ.

Doris R. Schwartz, 405–78 St., Brooklyn 9, N. Y., Public Health Nursing Interne, Red Hook-Gowanus Community Nursing Service

Marjorie L. Varner, R.N., 407 Maine, Lawrence, Kan., Public Health Nurse, Lawrence-Douglas County Health Dept.

Ethel J. Walder, M.S., Box 147, Angwin, Calif., Assoc. Professor and Head, Nursing Education Dept., Pacific Union College

Epidemiology Section

Milagros S. De Guzman, M.D., M.P.H., 75 M. Salvador, San Juan, Rizal, Philippines, Asst. Malariologist Supervisor, Philippines Government

C. D. Hopkins, M.D., 1420 Tampa St., Tampa, Fla., Asst. Director, Hillsboro County Health Dept.

Gordon Meiklejohn, M.D., C.M., 1392 University Ave., Berkeley 2, Calif., Research Associate, Viral and Rickettsial Disease Laboratory, State Dept. of Public Health

John M. Parker, M.D., D.P.H., Suffield, Alberta, Canada, Asst. Medical Officer of Health, East York-Leaside Health Unit

School Health Section

Cecelia G. Burns, R.N., 912 Wallis Ave., Farrell, Pa., School Nurse, Farrell Board of Education

Sister M. Chrysta, 8425 McNicholas Rd., West, Detroit 21, Mich., Instructor in Biology and Chemistry, Marygrove College

Kishore C. Patnaik, M.B., D.P.H., 1533 E. N. Ave., Baltimore, Md., Student, Johns Hopkins School of Hygiene and Public Health

Caswell L. Phillips, 42 Howe St., New Haven, Conn., Student, Dept. of Public Health, Yale Univ.

Francis E. Rothchild, M.S., 800 Louisiana, Little Rock, Ark., Supervisor of Health and Physical Education, Little Rock Public Schools

Erma Smith, M.D., Ph.D., College Station, Durham, N. C., Physician, Woman's College, Duke Univ.

Dental Health Section

Robert W. Anderson, D.D.S., City Hall, Chattanooga, Tenn., Asst. Dental Surgeon, U. S. Public Health Service

Joseph I. Freeman, D.D.S., 691 Massachusetts Ave., Arlington, Mass., Dentist

Marvin E. Mergele, D.D.S., 128 W. Commerce, San Antonio, Tex., Director, Dental Division, San Antonio Health Dept.

George W. Wyatt, D.M.D., State Dept. of Health, Charleston, W. Va., Director, Bureau of Dental Health

Medical Care Section

Murray Abowitz, M.D., 8766 Arlene Terrace, Los Angeles 46, Calif., Private Practice

Henry J. Bakst, M.D., 80 East Concord St., Boston 18, Mass., Asso. Professor of Preventive Medicine, Boston Univ. School of Medicine

John B. Barnwell, M.D., Rm. 866, Veterans Adm. Bldg., Vermont Ave. & H. St., N.W., Washington 25, D. C., Chief, Tuberculosis Division, Dept. of Medicine and Surgery

Pearl Bierman, M.A., 55 E. Superior St., Chicago 11, Ill., Chief Medical Assistant Consultant, Illinois Public Aid Commission

Ernst P. Boas, M.D., M.A., 1185 Park Ave., New York 28, N. Y., Private Practice

Paul F. Bourscheidt, Peaceful Acres, Mackinaw, Ill., District Manager, Blue Cross Plan

Henry G. Brickman, M.B.A., 8 Hampton Rd., Natick, Mass., Student, Dept. of Public Health, Yale Univ.

A.P.H.A. membership application blank on page XXXIII

EMPLOYMENT SERVICE

The following pages present information for those seeking qualified public health personnel and for those seeking positions in public health.

This is a service of the Association conducted without expense to the employer or employee.

Address all correspondence to the Employment Service, A.P.H.A., 1790 Broadway, New York 19, N. Y., unless otherwise specified.

POSITIONS AVAILABLE

TB Control Physician for Pacific Coast State Health Department. Minimum 3 years' experience in TB control work. Graduate of Class A medical school, 1 year internship, preferably supplemented by 1 year graduate study in school of public health leading to M.P.H. degree. $7,200 to start, advancing to $8,400. Considerable state-wide travel with maximum per diem of $7.50, plus 6¢ per mile for use of car. Civil Service status but no written exam required. Write Box A-45, Employment Service, A.P.H.A.

Assistant Medical Superintendent, TB Sanatorium. To assist in administration of 100 bed TB Sanatorium and outpatient chest clinic. Some previous experience in a TB institution required. Candidates must have license or procure license to practise in California before appointment. Salary range $549–686 monthly. Write: Civil Service Commission Court House, Redwood City, Calif.

Clinical Laboratory Technician to perform general bacteriological and serological examinations and various diagnostic tests under direction of Senior Technician. Current Clinical Laboratory Certificate issued by State of California must be obtained prior to appointment. Salary range $225–281 monthly. Write: Civil Service Commission, Court House, Redwood City, Calif.

Bacteriologist to perform water and milk laboratory examinations and general current bacteriological and serological laboratory work. Public Health Laboratory Technicians certificate issued by California must be obtained prior to appointment. Salary range, $252–314. Write: Civil Service Commission, Court House, Redwood City, Calif.

Health Educator for State TB Association in New England. Duties include consultant work with affiliated associations throughout state to promote community organization for health education and public health action. Master's degree in public health and/or health education is required. Please state salary expected. Write: (Mrs.) Sarah J. Schmidt, Director of Health Education, Massachusetts Tuberculosis and Health League, 1148 Little Bldg., Boston 16, Mass.

Local Health Consultant, 5 years employment in public health work including experience as health officer. Equivalent combinations will be considered. Salary $6,600–9,120. Appointment may be made at the minimum rate. Write: State Personnel Department, State Capitol, Hartford, Conn.

Laboratory Technician, male or female, for City Health Department Laboratory. Graduate of recognized training school, salary begins at $2,700 and increases to $3,110 after probationary period of 90 days. Retirement plan, vacation, and sick leave. State training and experience in bacteriology, serology, parasitology, and other related subjects. Write: R. L. Loftin, M.D., Director, Bay City Dept. of Health, City Hall, Bay City, Mich.

Public Health Officer, Grays Harbor County, Washington; entrance salary of $7,440 per annum with the range reaching $9,120. Hoquiam and Aberdeen are the principal cities of this county which has a population of about 55,000 and is located on the westernmost portion of the state bordering the Pacific Ocean. Write: Arthur L. Ringle, M.D., State Director of Health, 1412 Smith Tower, Seattle, Wash.

Public Health Officer for County Health Department. Beginning salary $12,000; salary range $12,000–15,000. Car provided. References, qualifications, experience, recent photograph required. Write: Box 1191, Joliet, Ill.

Bacteriological Technician to assist in the Bacteriology Department of the Research Division of a large pharmaceutical and biological firm. B.S. degree in Bacteriology and at least 1 year of experience. Experience in immunology or chemotherapy desirable. Salary starts at $58.40 per week. Write Box A-44, Employment Service, A.P.H.A.

Supervisors and Public Health Nurses, Baltimore County Health Department. Population 248,000; suburban, industrialized, and rural areas; county seat 8 miles from Baltimore. Generalized service including modern school health program, rapidly expanding up to 50 field nurses. One month's vacation; 5 day, 35½ hour week; sick leave; retirement plan. For

use of personal car, 7¢ per mile. Supervisors: degree and experience required; salary $3,200–$3,700; with additional preparation in child hygiene, venereal disease, mental hygiene, or orthopedics, $3,500–$4,000. Public Health Nurses: beginning salary $2,300 (for trainee) to $2,700, depending on experience and education; increases to $3,300. Write: Dr. William H. F. Warthen, Health Officer, Baltimore County Health Dept. Towson 4, Md.

Physician as Director City-County Health Department, population 56,000; staff of 14; well equipped offices and laboratory. Salary for man with degree in public health $7,500 plus 8¢ per mile travel. Write: City-County Health Dept., Safety Building, Eau Claire, Wis.

Sanitation and Public Health Engineer—*experienced man for tropical assignment.* Will work in connection with well established medical hospital. Should have background in malaria and nuisance control, laboratory testing, worm and infectious diseases. Attractive two year contract. Write for details to **Box A-43**, Employment Service, A.P.H.A.

Public Health Nurses needed by San Bernardino County; public health nurse's certificate required; car necessary, mileage allowed; salary $232–282 per month. Write: County Personnel Office, 242 Third Street, San Bernardino, Calif.

1. **Field Workers** for state office of voluntary health agency, Northeast. Salary range $3,000–3,800 or $3,800–4,800 depending on background.
2. **Executive Secretary** for local voluntary agency, Northeast; salary $4,000–$5,000. Health Education and community organization background required for both types of positions. Write **Box A-42**, Employment Service, A.P.H.A.

Health Director for Shiawassee County, Michigan. Population about 42,500. Write to J. R. Middaugh, Chairman Health Committee, Laingsburg, Mich.

Health Officer for agricultural county in eastern North Carolina; population 68,000; county seat has 4 year college, accredited high schools, staff of 10, salary open. Must meet North Carolina Merit System requirements. Prefer M.P.H. Write: J. H. Boyd, Jr., Mayor, Greenville, N. C.

Sanitary Engineer or experienced **Sanitarian** for rural district in Michigan. Starting salary $3,400 and mileage $600. Write: Saginaw County Health Dept. 1501 North Michigan, Saginaw, Mich.

Announcement

District Health Officers Wanted in New York City Health Department

The New York City Department of Health has 6 vacancies in the title of District Health Officer at the salary of $7,150 per annum. This position involves administrative responsibility for all activities of the Department of Health in a district with a population of approximately 250,000. Candidates must have an M.D. degree and 1 year of approved internship. In addition, they must have an M.P.H. degree and 3 years of experience as a health officer or assistant health officer, or in another administrative public health position; or a satisfactory equivalent of this education and experience. Local legislation requires 3 years of residence in New York City immediately prior to appointment. This requirement will probably be waived in the case of outstanding applicants. Interested applicants are to write to: Bureau of Personnel, New York City Department of Health, 125 Worth Street, New York 13, N. Y.

POSITIONS WANTED

Bacteriologist, M.S., minor chemistry, 9 years of extensive experience in research, clinical bacteriology, and industrial development. Interested in responsible position in public health, industrial laboratory or teaching institution. Write **Box L-D1**, Employment Service, A.P.H.A.

Sanitarian, B.S., M.P.H., male, 39, 8 years field and administrative experience in control of food, drugs, milk, and water in official health department. Interested in supervisory or administrative position in environmental sanitation program of official agency or industry. Minimum required salary $5,000 per annum. Write **Box E-7**, Employment Service, A.P.H.A.

Director of one of larger northern industrial city departments, with broad federal, state, and local experience; initiator of several unique and successful programs, desires change to south or southwest for climatic reasons. Will exchange and respect confidential correspondence preliminary to interview. Write **Box C-9**, Employment Service, A.P.H.A.

All communications should be sent to Burneice Larson, Medical Bureau, Palmolive Building, Chicago 11, Ill.

Opportunities Available

WANTED—(a) Professor of public health, foreign university; American citizen, qualified to speak Spanish fluently, required. (b) Public health director, health unit comprising two county areas; town of 8,000, short distances from university center, several large cities; Middle West. (c) Student health director; state university; 9,000 students. (d) Public health or tuberculosis specialist to serve as tuberculosis consultant in United States dependency. (e) Tuberculosis specialist to direct newly inaugurated program in large metropolitan area; $15,000. (f) Public health physician to direct new program; large organization; California. (g) Public health supervisors and staff nurses; newly established city and county health departments; salaries for former, $3,300–$4,800; for latter, $2,700–$3,900. PH2-1 Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

WANTED—(a) Dentist to direct health program of education, preventive and remedial; suburb, Middle West metropolis, university medical center. (b) Dental consultant; state department of health; should be qualified to develop program for children; Southwest. (c) Dentist to conduct rural health dental program; Southeast. PH2-2 Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

WANTED—(a) Health Educator; Chicago area. (b) Sanitary engineers, public health engineers and specialists in fields of malaria and insect control; positions of considerable responsibility; South America. (c) Sanitarian; county health department; California. (d) Health educator; university medical center; New England. (e) Sanitary engineer; state department of health; West. PH2-3 Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

WANTED—(a) Public health nurse supervisor; generalized program, including tuberculosis division, school program; university town, California. (b) Educational supervisor; city health department; vicinity New York City. (c) Public health nurse consultant; state service for crippled children under direction of university medical school. (d) School nurse to direct health program; county schools; headquarters in university town; Pacific Northwest. (e) Public health supervisors and staff nurses; modern health centers; South America; knowledge of Spanish, Portuguese or French desirable. PH2-4 Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

Opportunities Wanted

Public health physician seeks directorship; M.P.H., Johns Hopkins; seventeen years' public health experience, including important assignment abroad; for further information, please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

Dentist experienced in public health work; eight years in charge of dental division, county health department; for further information, please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

Health educator or coördinator; Master's in Public Health; two years, health educator, liberal arts college; for further information, please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

Sanitary engineer; B.S. in Bacteriology; twelve years, sanitary engineer, large industrial company; for further information, please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

Public health specialist; M.S.P.H. (Major: health education), Yale; eight years, Professor of Health Education and Health Educator, small college; for further information, please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

Public health nurse seeks administrative position; M.A., Public Health Nursing; six years, educational supervisor, city health department; eight years, nurse consultant, state board of health; for further information, please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

NEWS FROM THE FIELD

SUMMARY OF REPORT OF THE TASK FORCE COMMITTEE ON FEDERAL MEDICAL SERVICES TO THE COMMISSION ON ORGANIZATION OF THE EXECUTIVE BRANCH OF THE GOVERNMENT

One section of the work of the United States Commission on Organization of the Executive Branch of the Government, commonly known as the Hoover Commission, was charged with a study of federal medical services. Former President Herbert Hoover released, on December 26, a summary of the report of the Task Force on Federal Medical Services. Its purpose, he said, was to indicate the organizational problems with which the government is confronted. The report represented almost a year's work.

Mr. Hoover said that we all want veterans and members of the armed services to have first rate medical care and that the problem is to provide such care without overtaxing our limited number of trained physicians and other medical resources. This means that we must eliminate waste in the use of these physicians and in the use of these resources. Unless we do this, veterans, civilians, and servicemen alike will suffer.

Mr. Hoover made it clear that Task Force findings do not necessarily represent the final conclusions of the Commission, which is obligated to make a pattern of the Government as a whole, and it is not always possible, he said, to fit special points of view into the general pattern.

The personnel of the Task Force on Federal Medical Services included, under the Chairmanship of Hon. Tracy S. Voorhees, Assistant Secretary of the Army, 16 members of the committee, plus a professional staff. Among those best known in public health were Edward D. Churchill, M.D. of Boston; Robin C. Buerki, M.D., of Philadelphia; Paul R. Hawley, M.D., of Chicago; Hugh R. Leavell, M.D., of Boston; William C. Menninger, M.D., of Topeka; Hugh J. Morgan, M.D., of Nashville; Alfred N. Richards, Ph.D., of Philadelphia; Allen O. Whipple, M.D., of New York and Ray Lyman Wilbur, M.D., of Palo Alto. The staff consisted of Howard M. Kline, Ph.D., as Executive Director, recently a member of the staff of the A.P.H.A. Subcommittee on Medical Care, with Jack R. Ewalt, M.D., in neuropsychiatry; Richard Nauen, M.D., and Edward X. Mikol, M.D., for tuberculosis; Julius Comroe, Jr., M.D., for research; James Troupin, M.D., for preventive medicine; E. Richard Weinerman, M.D., for hospitalization; plus specialists in medical supply.

I. MAGNITUDE OF THE PROBLEM

In 1948 more than forty-four federal agencies spent about 1¼ billion dollars for health and medical services. The federal government now assumes a varying degree of care for some 24,000,000 persons, about one-sixth of our population.

II. WEAKNESSES OF THE PRESENT SYSTEM OF ORGANIZATION OF FEDERAL MEDICAL SERVICES

The present program is devoid of any central plan. The federal government is assuming uncalculated obligations without any understanding of their ultimate cost, the lack of the necessary professional man power to carry them out or their adverse effect upon the hospital system of the country. There must be overall planning and this in turn requires first, a clear definition of the extent of the responsibilities, and second, an organization appropriate to carry out the commitment.

A. *Defects Revealed by Area Studies*

In the New York City area it was found that four Army and Air Force hospitals could be closed, reducing the requirements for medical officers by 80 per cent, yet at the same time a higher standard of service would be provided. Several federal agencies are planning to build hospitals in this area to cost $100,000,000, meaning a doubling of the permanent plant. There is no evidence that such additional beds are needed.

In the San Francisco area there are 13 federal hospitals with a constructed capacity of 9,900 beds, but they have only 4,200 patients at present. Seven of these 13 hospitals could be closed since only 42 per cent of their constructed capacity is utilized.

In Honolulu the Army has just completed a hospital costing $37,000,000, although the Navy has close by a permanent hospital plant adequate for all military needs in that area. Under proper planning practically all of the expenditures for the Army Hospital since the war could have been avoided.

B. *Defects on the Basis of Diseases*

For tuberculosis and neuropsychiatric cases (which now occupy 60 per cent of the Veterans Administration's beds) the present organization is unsatisfactory. There is an acute shortage of medical personnel aggravated by unsound organization. Duplication results in inefficiency, and there is imperative need for unification.

C. *Shortcomings in Construction Program*

The Veterans Administration has a hospital construction program that will cost $1,100,000,000. These hospitals will cost from $20,000 a bed to as high as $51,000 per bed depending on the size and location. "V.A.'s program conflicts with the government's policy under the Hill-Burton Act of aiding non-federal hospitals for the purpose of establishing a further hospital system for the country as a whole."

D. *Defects Relative to the Length of Stay of Patients*

Compared with representative voluntary hospitals, patients with the same diagnosis stay in government hospitals two or three times as long. Under a unified system with proper planning the period could be greatly shortened.

E. *Shortcomings in the Use of Medical Man Power*

In the Armed Forces a great shortage of medical personnel exists. Within six months it will be accentuated because medical personnel trained at government expense will be completing their required tour of duty. A draft of medical personnel is needed, but it will bring in only young doctors who cannot provide high-grade specialized care. Among the non-military federal agencies, no one has the necessary man power. This condition is neither *temporary nor self-correcting*. Construction of the Veterans Administration hospitals is far outrunning the available man power. These shortages are intensified by present organization and practices which make for inefficiency in utilizing professional personnel.

F. *The Problem of Federal Beneficiaries*

A large plant is being built to serve groups of beneficiaries to whom the federal obligation is not clearly defined. About 900,000 Army and Air Force dependents receive complete medical care on no basis other than an appropriation act passed more than sixty years ago authorizing medical officers to care for dependents "whenever practicable." Concerning veterans with non-service connected disabilities, there is an authorization to hospitalize them only if beds are "available." Nevertheless, 100,000 Veterans Administration hospital beds have been built or authorized which serve no purpose except deliberately to make beds available for non-service connected cases. Most of this hospitalization could be more efficiently provided in community hospitals on a reimbursable basis.

III. RECOMMENDED ORGANIZATION TO ACHIEVE OBJECTIVES DEFINED BY CONGRESS

For the non-military system it is recommended that a National Bureau of Health should be established within the Cabinet Department embracing health, education and security. This Bureau of Health should be headed by a professional career Director General, who should report directly to the Secretary of the Department. This Bureau should be composed of three main divisions:

1. Medical Care, which would include all functions of hospitalization and other direct medical care of patients
2. Public Health Division
3. Research and Training Division

IV. MEDICAL CARE FUNCTIONS OF THE NATIONAL BUREAU OF HEALTH

To the Medical Care Division of the Bureau there should be transferred the following:

1. All general hospitals of the Armed services and most station hospitals except those at outlying posts
2. The medical functions of the Veterans Ad-

ministration, in toto, including the outpatient service in the Regional Offices
3. The hospitals of the Public Health Service
4. St. Elizabeths Hospital

Each of the armed services should maintain one medical and teaching hospital, overseas hospitals, and some station hospitals. The hospitals of the Bureau of Indian Affairs and the Bureau of Prisons should not be transferred, but they should be manned by personnel from the National Bureau of Health. The transfer of the general hospitals of the armed services is justified partly because a large number of the patients in them are of little further military value. The transfer of the Veterans Administration hospitals is justified under the Commission's instructions to place like functions, where possible, together. If they are to remain separate, the Bureau of Health would be a central health agency in name only.

V. INTEGRATION OF FEDERAL HOSPITALIZATION SYSTEM WITH NON-FEDERAL HOSPITALS

The present inconsistencies in policy between the Veterans Administration and other federal construction programs and the non-federal hospitals under the Hill-Burton Act should be ended. Inadequacies exist in the nation's hospital plant. The federal government believes that there is need for doing something about them. This policy could be furthered by placing federal cases in non-federal hospitals on a reimbursable basis wherever it is efficient to do so instead of further enlarging the federal hospital plant. Where facilities do not exist they can be constructed on a grant-in-aid basis with much less cost to the federal government than by direct construction and operation. The average total cost of construction per hospital bed for private hospitals is about $16,000, whereas in federal hospitals it is between $20,000 and $30,000. Also this would tend to relieve the financial difficulties of private hospitals.

VI. NEED FOR RECONSIDERATION OF THE DEFINITION OF BENEFICIARIES

In planning future medical services Congress should clearly define the beneficiaries. As to dependents of persons in the armed service the same policy must apply to all three services. Such care is really a part of the compensation of persons in the armed service.

As to veterans with non-service connected disabilities, the present situation is inequitable to veterans and unsound and expensive for the government. Such care should be furnished in those facilities, whether federal or local, in which it can be given most efficiently. Congress should make a decision on whether medical service should be extended to all veterans irrespective of financial need or to those with non-service connected disabilities only if they are in financial need. "In any case, there is no need for financial screening of chronic cases, as substantially all of these are soon made medical indigents by their disease. They would be a charge on the public in any event."

VII. ORGANIZATION OF MEDICAL SERVICES IN THE ARMED FORCES

Unification of medical services in the various armed forces would be most efficient, but medicine alone cannot be merged. Consequently such consolidation must be geared to the extent of unification of the services themselves. Much duplication can be avoided by assigning responsibility in each overseas area to one service to give hospital care for all. Supervision of armed forces medical services should be in the hands of a Deputy of the Secretary of Defense. These suggestions would greatly relieve the demand for personnel for armed service medical service. Nevertheless, this reduction in requirements would not be sufficient to avert a draft of medical personnel.

VIII. HEALTH RESOURCES AND MAN POWER ALLOCATION IN TIME OF EMERGENCY

The plan that has been outlined above would be a significant measure to promote national defense. It would make possible the optimum utilization of medical man power by a full integration of the federal hospital system with non-federal hospitals. It would make possible a further saving of medical man power. Where atomic warfare is a potential threat it is not feasible to take medical practitioners from their home communities. To do so would imperil civilian defense.

IX. PUBLIC HEALTH FUNCTIONS OF THE NATIONAL BUREAU OF HEALTH

In the Public Health Division of the proposed National Bureau of Health the following activities would be consolidated. From the Public Health Service the following would be transferred: the Bureau of State Services and quarantine activities of the Bureau of Medical Services, the Biologics Control Laboratory and the Offices of Sanitary Engineering and of Dentistry from the Office of the Surgeon General. The Food and Drug Administration would also be a part of the Public Health Division.

The main functions of the Public Health Division would be

a. To administer grants-in-aid.
b. To conduct a clearing house of information on public health activities.
c. To regulate Interstate Commerce in foods, drugs, and medicines.

The federal grants-in-aid for public health have proved extremely useful. They have stimulated state and local expenditures for public health. The federal share of such expenditures has fallen from 46 per cent in 1937 to 29 per cent in 1946. It is recommended that in the future these grants should be made on a more general basis. The federal structure for administering grants should be simplified and decentralized, with minimum supervision of the states consistent with sound planning and administration. The grants-in-aid administered by the Children's Bureau should not be transferred immediately. "It is the view of your committee that it [the Children's Bureau] should function as a staff unit directly responsible to the secretary of the proposed department, rather than having its health and other functions split and united with the major component units of the Deparement." In not more than three years the administration of grants for maternal and child health and crippled children should be consoldiated with the other health grants-in-aid administered by the Public Health Division.

The *Meat Inspection Service now in the* Bureau of Animal Industry should remain there.

X. RESEARCH AND TRAINING IN THE NATIONAL BUREAU OF HEALTH

Because research and medical education are a necessary part of any broad medical program, a Division of Research and Training should be created in the Bureau. In the administrative control of research there is need for a certain looseness and flexibility. Nevertheless, some coördinating mechanism is needed under which research activities that are truly vital to the national welfare may be considered. In the armed services a committee on medical sciences has been created by the Research and Development Board.

In the non-military field a comparable committee should be created consisting of representatives of the Divsiion of Research and Training of the new Bureau, along with representatives of the Atomic Energy Commission and of the Department of Agriculture.

There should also be created a new Interagency Committee on Medical Sciences composed of representatives of the above mentioned group and the group from the military services. This committee should be concerned primarily with grants-in-aid and institutional grants to non-federal institutions. It is also recommended that a National Science Foundation should be established primarily as a means of insuring strength in the basic sciences.

The proposed Division of Research and Training should conduct directly laboratory and basic research, administer grants-in-aid in this field and act as a clearing house of information. The work of the National Institutes of Health should be transferred to it, and it should operate the proposed Clinical Research Center of the Public Health Service.

XI. PERSONNEL POLICIES IN FEDERAL MEDICAL SERVICES

A new overall medical service should be organized for the federal government. The nucleus for this would consist of the medical personnel of the VA hospitals, the commissioned personnel of the Public Health Service and all medical professional personnel employed under Civil Service. "It would be impracticable to make this a commissioned corps." Members of the commissioned service of the Public Health Service should be given the option of positions in the new service or of continuing in their present status "but no new commissions should be issued."

"The new system should put into the hands of the National Bureau of Health the full responsibility for recruiting, selecting, assigning and otherwise handling its own professional personnel." The Civil Service has never functioned effectively in providing an adequate professional career service for medical and ancillary personnel partially because of its rigidity, slowness and lack of opportunity for promotion.

XII. AID TO MEDICAL EDUCATION

Many medical schools are now in serious financial condition. Government financial aid is now an urgent necessity. Adequate facts on which to distribute such aid are not available. The Public Health Service should make a short-range survey to determine the exact needs and how they should be met. Care must be taken in granting aid to maintain the professional independence and the initiative of the schools. Also the aid should be given in such a way as to increase the output of trained personnel especially in the areas where there are acute deficiencies.

XIII. MEDICAL SUPPLY

A unified supply system for medical items would effect great savings.

XIV. PROVISION FOR CONTINUING STUDY AND TOP LEVEL SUPERVISION OF FEDERAL MEDICAL SERVICES

It is necessary to establish some means of coördinating military and non-military federal organizations in the medical field.

XV. THE NEED FOR INCREASED EMPHASIS ON THE CONTROL OF DISEASE

The outlook is most alarming concerning the costs of medical care and the needs for hospitalization if we consider medical care in terms of its organization as it exists today. One important factor that would directly reduce costs for hospitalization is the relative increase in the provision of ambulatory care. At present the government apparently is committed to a reverse policy. The second course open is through research and development in public health and preventive medicine. Here the federal government can lend assistance. Preventive medicine must be widely defined as including both special measures that protect the individual from contracting a disease as well as measures for the prevention of death and disability, and the early recognition and treatment of disease that is already established.

As an example of the savings that can result from preventive medicine, some 50,000 more persons would have died of diphtheria in 1947 if the 1900 mortality rates had prevailed. The cost to the nation in 1947 would have been $30,000,000 as against an actual expenditure of $600,000. "We stand confident then in the recommendation of a courageous approach to the control of chronic disease, rather than a passive acceptance of the immeasurable cost that lies ahead. Funds invested in research and education at this time will not only return dividends in dollar savings in the future, but a still greater reward in health and productivity in the nation."

XVI. CONCLUSION

"We have attempted to outline a method which we hope will correct the extravagance resulting from the present series of unrelated projects, and weld these together into an integrated, orderly whole. With such an organization, staffed by outstanding personnel, it should be possible to utilize our unequaled medical resources to the maximum, and by intelligent planning take steps which will make us a healthier and stronger nation."

PAN AMERICAN SANITARY ORGANIZATION MEETS

The Directing Council of the Pan American Sanitary Organization met in Mexico City, October 8–12. It adopted a budget of $1,700,000 for the year 1949 for its operating unit, the Pan American Sanitary Bureau. Approximately 30 per cent each, of this budget, is designed for field programs for the control of communicable diseases, and for central service and field activities, and approximately 20 per cent each for headquarters administration, and for zone offices.

At this meeting also a report was made on relations with the World Health Organization which will be the basis for the agreement between WHO and the Pan American Sanitary Organization. The director of the Pan American Sanitary Bureau is authorized to sign this agreement as soon as 14 of the 21 American nations have ratified the Constitution of the World Health Organization. Nine nations have ratified, the most recent one being Argentina on October 22. The Directing Council of the Pan American Organization recommended to its remaining members the desirability of ratification so that the viewpoint of the American continent might be duly represented in WHO deliberations.

This meeting also took action on non-self-governing territories, which by resolution, were granted the right to participate without vote in the deliberations of the plenary sessions of the Directing Council; to participate with voting rights in committees of the Directing Council except in matters of administration, finances, and the constitution; to participate on the same basis as members in matters relating to procedure in the sessions of the Directing Council and its committees; and to propose subjects for the agenda of meetings of the Directing Council.

Lima, Peru, was designated as the seat of the 1949 meeting of the Directing Council.

The following officers were elected at a preliminary session of the Executive Committee:

Chairman: Mexico, Dr. Ignacio Morones Prieto
Vice-Chairman: Peru, Dr. Jorge Estrella Ruiz
Secretaries: Pan American Sanitary Bureau, Dr. Miguel E. Bustamante; Mexican Delegation, Dr. Jose Zozaya

Representatives of the 19 countries present at the meeting were:

Argentina, Dr. Alberto Zwanck
Bolivia, Dr. Nestor Salinas Aramayo
Brazil, Dr. Heitor Praguer Froen
Colombia, Dr. Jorge Boshell Manrique
Costa Rica, Dr. Gonzalo Gonzalez Murillo
Cuba, Dr. Luis Espinosay G. Caceres
Dominican Republic, Dr. Luis F. Thomen
Ecuador, Dr. Roberto Nevarez Vasquez
El Salvador, Dr. Rafael Vega Gomez
Guatemala, Dr. Luis F. Galich
Honduras, Dr. Daniel Meza Zelaya
Mexico, Dr. Ignacio Morones Prieto
Nicaragua, Dr. Jacinto Jimenez
Panama, Dr. Guillermo Garcia de Paredes
Paraguay, Dr. Raul Pena
Peru, Dr. Jorge A. Estrella Ruiz
United States, Dr. Thomas Parran
Uruguay, Dr. Ricardo Cappeletti
Venezuela, Dr. Alfredo Arreaza Guzman

The Pan American Sanitary Bureau's Director, Dr. Fred L. Soper; the Assistant Director, Dr. John R. Murdock, the Secretary General, Dr. Miguel E. Bustamante; the Chief of the Lima Regional Offices, Dr. Anthony Donovan; and its nursing consultant, Mrs. Agnes M. Chagas, among others, were present. The final report was signed for the United States by Leonard A. Scheele, Surgeon General of the U. S. Public Health Service, serving as an alternative representative for his country.

Observers were present as follows:

World Health Organization: Dr. Frank A. Calderone, Director, New York Office
Holland: Dr. C. Van Den Berg, Director General of Public Health
French Antilles: Dr. Rene Goulley, Ministry of Health
British Caribbean Territories: Dr. Joseph W. P. Harkness, Medical Adviser
Netherlands West Indies: Dr. Jacob Rudolph Arends, Chief, Health Services
Surinam: Dr. Anton Eduard Wolff, Chief, Bureau of Communicable and Endemic Disease Control

DR. ARMSTRONG RECEIVES PRENTISS AWARD

At a luncheon meeting of the Health Education Section, American Public Health Association, in Boston on November 9, Donald B. Armstrong, M.D., 2nd Vice President of the Metropolitan Life Insurance Company in charge of health and welfare services, received the fifth annual Elisabeth S. Prentiss National Award in Health Education, for outstanding achievement in the health education field. The presentation was made by Lester Taylor, M.D., president of the Cleveland Health Museum.

The Museum's Award Committee based its selection of Dr. Armstrong upon a wide range of accomplishments. His 1916 survey and study led to the establishment of the world's first health demonstration, the Framingham, (Mass.) Community Health and Tuberculosis Experiment. This proved that a community can stamp out tuberculosis, and paved the way for control in this and other countries. His survey in 1920 resulted in the first National Health Council which he headed for several years. As Secretary of the Milbank Memorial Fund Technical Board he conducted health demonstrations in several New York State cities.

In receiving the Award, Dr. Armstrong paid a tribute to his staff. "It is the members of this staff," he said, "rather than one involved in administrative policies, who really contribute and execute ideas and effective action in health education. These associates of mine are the real winner of this award."

SURVEY OF MEDICAL EDUCATION

A three year survey of medical education was begun on January 1 jointly by the Association of American Medical Colleges and the Council on Medical

Education and Hospitals of the American Medical Association. The full-time director of the survey is John E. Deitrick, M.D., also professor of medicine at Cornell University Medical College and active for many years in cardiovascular research.

The objectives of the study are stated to be "to evaluate the present programs and determine the future responsibilities of medical education" in order to:

1. Maintain the best physical and mental health standards of all the people.
2. Assess the degree to which medical schools are meeting the needs of the country for physicians.
3. Promote the advancement of knowledge in the field of medical science.
4. Inform the public fully about the nature, content, and purposes of medical education.

The members of the joint committee of seven who will supervise the study are:

Dr. Alan Valentine, Chairman, President, University of Rochester
Dr. Donald G. Anderson, Secretary, Council on Medical Education and Hospitals, American Medical Association
Dr. Arthur C. Bachmeyer, Associate Dean, University of Chicago School of Medicine
Dr. Joseph C. Hinsey, Dean, Cornell University Medical College
Dr. Victor Johnson, Director, Mayo Foundation for Medical Education and Research, Rochester, Minn.
Dr. Dean F. Smiley, Secretary, Association of American Medical Colleges
Dr. Herman G. Weiskotten, Dean, Syracuse University College of Medicine

WHO NOW INCLUDES 57 NATIONS

It was announced at headquarters of the United Nations at Lake Success, N. Y., on January 6, that Paraguay had joined the World Health Organization to become the 57th member of the group.

t was pointed out that Paraguay is tenth member of the Organization American States to join WHO. When rteen American republics have joined, ormal integration is to be effected between the WHO of the United Nations and the Pan American Sanitary Bureau, which will serve as a regional agency of WHO.

NEW YORK STATE HEALTH CONFERENCE MOVES TO LAKE PLACID

Herman E. Hilleboe, M.D., New York State Commissioner of Health, has announced that Lake Placid, N. Y., has been chosen by the State Department of Health as the location for the 45th Annual Conference of Health Officers and Public Health Nurses. The 1949 conference dates will be June 20–23 and will include meetings of the State Health Officers Association and the Association of School Physicians.

The conference has for many years been held in Saratoga Springs, where registration in recent years has exceeded 1,500.

INTER-AMERICAN CONGRESS ON BRUCELLOSIS

The Second Inter-American Congress on Brucellosis, under the auspices of the Pan American Sanitary Bureau, was held at Mendoza and Buenos Aires, Argentina, November 17–26, 1948. The United States was represented officially by Dr. James H. Steele, Chief, Veterinary Public Health Division, Communicable Disease Center, U. S. Public Health Service, who was named Chairman of the Delegation, and Dr. C. K. Mingle, Assistant Chief, Tuberculosis and Brucellosis Eradication Division, Bureau of Animal Industry. Other American participants who were invited by the Congress were Dr. Harold Harris, New York City. Dr. Horace Powell, Indianapolis, Ind., Dr. Leo Lowbeer, Tulsa, Okla., and Dr. Joseph Griggs, Claremont, Calif.

The meeting at Mendoza was devoted to research and epidemiology papers by representatives of Argentina, Chile, Colombia, Peru, Venezuela, Mexico, and the United States. Dr. Steele presented

a paper on The Epidemiology of Brucellosis in the United States at this meeting. Dr. Mingle responded at the opening session for the visiting delegates to the speech of welcome by the Minister of Health, Dr. Luis Carrillo. Dr. Carlos Grivellari, Director of Public Health, Argentine Republic, was chosen President of the Congress. Dr. Miguel Bustamente, Secretary, Pan American Sanitary Bureau, was assisted by Dr. M. Ruiz Castaneda, Secretary.

In the Mendoza area, which is in the foothills of the Andes, there is an extensive goat industry and most of the brucellosis reported is of the melitensis type. The delegates had an opportunity to visit the surrounding country to see the goat industry and observe the conditions under which the shepherds became infected. The close proximity to human habitation of the corrals and the necessary handling of the animals when they are milked create conditions which allow for human exposure to animal infection. In the urban areas many human cases are traced to unpasteurized cheese of goat origin. There are very few cattle or swine in this region and no human *Brucella abortus* or *Brucella suis* cases are reported.

The meetings were resumed in Buenos Aires on November 22, and closed on November 26. The Buenos Aires session was mainly concerned with the discussion of the diagnosis and therapy of human brucellosis. Dr. Harris spoke on the Diagnosis and Treatment of Brucellosis; Dr. Griggs on Bacterial Allergy; Dr. Powell on Therapy; and Dr. Lowbeer on The Pathology of Swine Brucellosis. Dr. M. Ruiz Castaneda of Mexico, presented an excellent paper on The Treatment of Brucellosis with Aureomycin. The Congress acted to create two permanent committees to study the problems of standardization of human serological diagnostic methods and animal disease eradication. The success of both these study groups will depend upon having a standard antigen with which to compare other antigens. The Congress believed that the antigen of the Bureau of Animal Industry, U. S. Department of Agriculture, would be the best standard to use inasmuch as it is available in very large quantities and could be readily distributed. Similar studies will also be carried on for animal serology. The Congress further agreed that the disease could not be controlled in man until it was controlled in animals.

The Second Inter-American Congress on Brucellosis unanimously voted to accept the invitation of the United States to hold the Third Inter-American Congress on Brucellosis in Washington, D. C., in October, 1950. Dr. William W. Spink, of Minneapolis, Minn., has been named Chairman of the Third Inter-American Congress on Brucellosis, and Dr. M. Ruiz Castaneda will continue as Secretary.

ARKANSAS PUBLIC HEALTH ASSOCIATION

The first Annual Meeting of the Arkansas Public Health Association was held in the Robinson Memorial Auditorium, Little Rock, December 9–11, 1948, under the Presidency of Edgar J. Easley, M.D. Registration exceeded 375 from a total paid individual membership of 700, including at least 25 organizational memberships.

It is understood that the Association is primarily interested at the present time in developing citizen support, performing some of the functions of a state health council. Out of state speakers included Felix J. Underwood, M.D., State Health Officer of Mississippi; C. C. Applewhite, M.D., Medical Director, U. S. Public Health Service, New Orleans; Edythe P. Hershey, M.D., Regional Medical Director, U. S. Children's Bureau, Dallas, Tex.; Wilson G. Smillie, M.D., Cornell Medical College, New York City; and Roscoe P. Kandle, M.D., Field Director, American Public Health Association, New York.

COUNSELLING IN NURSING SCHOOLS

Through a grant from the W. K. Kellogg Foundation, the Western Reserve University School of Nursing is exploring counselling programs. In a series of eight monthly evening lecture-discussions led by counselling experts, about 300 graduate nurses and nursing school faculty members in the Cleveland area are discussing their interest in counselling. Four of the series are still to be held. Further information from Elva H. Evans, Series Secretary, 2063 Adelbert Road, Cleveland 6.

DR. SHEPARD TO UPPSALA UNIVERSITY

In September a new policy was inaugurated by the National Institutes of Health of sending promising young research officers to outstanding laboratories both in the United States and abroad for further study and collaborative research with renowned scientists.

The first of such trainees, Charles C. Shepard, M.D., of the Division of Infectious Diseases, has been accepted by Uppsala University, Sweden, for special training in chemical biophysics under the tutelage of Professor Arne Tiselius, who has a world-wide reputation as teacher and investigator in this field.

FULLER AWARD TO ENGINEER CUNNINGHAM

The Fuller Award of Merit, given annually by the American Water Works Association for distinguished service in the water works field, was recently presented to M. B. Cunningham, Superintendent and Engineer of Oklahoma City. The presentation was made at the annual meeting of the Southwest Section, AWWA, in Galveston in October at which the following officers were elected:

Director: M. B. Cunningham
Chairman: Delbert W. Robinson, Water Works Engineer, Community Public Service Company, Fort Worth, Tex.
Vice Chairman: J. R. Pierce, General Water Works Corporation, Pine Bluff, Ark.

AN INTENSIVE VD CAMPAIGN IN NEW YORK CITY

Early in November, 1948, the New York City Department of Health, in cooperation with the State Health Department, the county medical societies, and the U. S. Public Health Service began an intensive case finding and public information program on venereal diseases.

The 9 point program includes:

1. Organization of community groups, particularly in high VD rate areas, to which literature, display material, lectures, etc., will be supplied.
2. The encouragement of routine blood tests of all new patients by private physicians.
3. Encouragement of routine blood tests industry-wide.
4. Information service to labor unions.
5. Coöperation with colleges and universities in their interest in the scientific, educational and social aspects of VD.
6. Assistance to welfare agencies in their VD programs.
7. Treatment of VD patients by private physicians and in clinics rather than in hospitals to be encouraged.
8. Facilities for free treatment at social hygiene stations wherever necessary.
9. A long range program for the permanent display of posters, especially in places of employment.

By early December, the Commissioner of Health, Harry S. Mustard, M.D., described the program as an "unqualified success." The number of persons coming to social hygiene clinics more than doubled during the first month, and requests for free penicillin rose 400 per cent. In reporting to the Mayor, Dr. Mustard said,

> These results were made possible by the citizens of this city, the business and labor organizations, religious groups, civic bodies, educational institutions, and our colleagues in other city departments. The keen awareness of the difficulties of the problem, and the courageous acceptance of the duties imposed in an educational campaign of this nature, are tributes to the greatness of the people of this city. The medical profession made important contributions, both in terms of treatment and education. . . . Special commendation must be reserved for those great media of communi-

cation—the press, the radio, the motion picture, television, and bill boards—which set aside taboos and attacked the problem forthrightly and intensively. Two other great media, the subway car cards and the giant electric signs—both so peculiarly New York's own—made significant contributions.

FLUORINE TREATMENT IN NEW YORK CITY

A program of reducing tooth decay by fluorine treatment was begun in October by the New York City Health Department. Topical application is being made to the teeth of 50,000 preschool and school children attending health department clinics in 105 schools and 14 district health centers. This treatment is recommended by the American Dental Association and the U. S. Public Health Service. Dentists are being urged by the health department to use topical application of 2 per cent sodium fluoride solution as an aid in caries control.

NURSE RECRUITMENT ACHIEVES SUCCESSFUL RESULT

The National League of Nursing Education, New York, announces that over 700 groups throughout the country have been stimulating the recruitment of student nurses. In 1948, 43,000 new student nurses were enrolled, which is a total of 5,000 more than in 1947.

According to the League, during the past two years the responsibility for promotion was assumed by the American Hospital Association, assisted by the Advertising Council. Beginning in 1949, central planning will be carried on by the nursing organizations, with the League having responsibility for administering the project.

NEW APPOINTMENTS AT THE AMERICAN HEART ASSOCIATION

Two new appointments have been made at the American Heart Association. On January 15, John W. Ferree, M.D. became Director of the Public Health Division of the Association, a new position created to emphasize and promote the public health aspects of the Association's program. A second appointment on January 1 was that of Rome A. Betts as Executive Director. These are the first two appointments since the recent reorganization as a national voluntary health agency with state and local affiliates throughout the United States.

Since early 1947, Dr. Ferree has been Associate Director of the National Health Council, of which the Heart Association is one of the member agencies. As the National Health Council staff representative on the National Advisory Committee on Local Health Units, he was largely responsible for the Indiana and Salt Lake City regional conferences on Local Health Units of the past year, which brought together representatives of diverse lay groups to stimulate action for improving community health services.

Besides his National Health Council background, Dr. Ferree brings to his new job experience as a practising physician, as a state health officer, as a venereal disease control officer of the U. S. Navy during the recent World War, and as Director of Educational Services of the American Social Hygiene Association. He is a Fellow of the American Public Health Association, American Medical Association, and American College of Physicians.

Mr. Betts has been General Secretary of the American Bible Society since 1942, and Associate Secretary for five years previously. He is President of the Protestant Film Commission, and a member of the City Council of Summit, N. J.

Charles A. Connor, M.D. will continue as the Medical Director of the Heart Association with special responsibilities in the field of cardiac research. The Association will conduct a drive from February 7 to 28 for a $5,000,000 fund to study and combat diseases of

the heart and circulation, which have now moved to first place as a cause of death.

MICHIGAN PUBLIC HEALTH ASSOCIATION

The 28th Annual Michigan Public Health Conference was held in Grand Rapids, December 1–3, with a registration of 600 and an attendance averaging about 1,100. The theme of the meeting was community participation in health activities and the program was built around Michigan's favorable experience in this direction.

Among those on the program were Edwin G. Williams, M.D., Chief, Radiological Health Branch, Office of Engineering Activities, U. S. Public Health Service, who discussed Public Health Aspects of Atomic Energy; Richard F. Boyd, M.D., Medical Officer, Welfare and Retirement Fund, United Mine Workers of America, formerly Illinois Director of Local Health Services, who discussed The Health Department of Today and Tomorrow; Herbert J. Dunsmore, newly appointed Public Health Engineer of Pittsburgh Department of Public Health, who discussed The Community Working Together: In Housing; and the newly appointed Michigan Commissioner of Health, Albert E. Heustis, M.D., who opened the Conference. Roscoe P. Kandle, M.D., Field Director of the American Public Health Association, brought the greetings of the Association and served as summarizer of the Conference.

The Conference voted a fund of $500 for educational purposes regarding health units, particularly to work for additional state subsidies to local health districts.

The newly elected officers are:

President: Lyman Chamberlain, Sanitarian, Eaton County Health Department
President-Elect: C. C. Slemons, M.D., Director, Grand Rapids Health Department
Vice-President: James M. Gasoway, D.D.S., Dentist, Children's Fund of Michigan
Secretary-Treasurer: Marjorie Delavan, Director, Bureau of Education, Michigan Department of Health
Representative to A.P.H.A. Governing Council: David Littlejohn, M.D., Director, Wayne County Health Department
Directors: J. G. Molner, M.D., Detroit Health Department; Georgina Reid, R.N., Wayne County Health Dept.

AMERICAN COUNCIL ON RHEUMATIC FEVER ELECTS OFFICERS

The American Council on Rheumatic Fever, which was created in 1944 to correlate the interests of various voluntary health organizations concerned with rheumatic fever and rheumatic heart disease, and to coördinate these efforts with similar activities in the field, has recently announced officers for 1949. The Council is organized under the American Heart Association and there is interlocking membership in the governing bodies of the Council and the Association.

Rustin McIntosh, M.D., has been elected Chairman of the American Council on Rheumatic Fever for 1949. Dr. McIntosh is Carpentier Professor of Pediatrics at the College of Physicians and Surgeons, Columbia University, New York City. Lawrence Linck of Chicago was elected Vice-Chairman. Among the newly elected members of the Council's Executive Committee are:

Walter Bauer, M.D., Boston
David D. Rutstein, M.D., Boston
T. Duckett Jones, M.D., New York
Homer F. Swift, M.D., New York
George M. Wheatley, M.D., New York

The organizations belonging to the Council include:

American Academy of Pediatrics
American Association of Medical Social Workers
American College of Physicians
American Heart Association
American Hospital Association
American Medical Association
American Nurses Association
American Public Health Association
American Rheumatism Association
American School Health Association

National Organization for Public Health Nursing
National Society for Crippled Children and Adults.

A.M.A. ADOPTS DEFINITION OF PUBLIC HEALTH

The House of Delegates of the American Medical Association at its meeting in St. Louis on December 1, upon recommendation of its Reference Committee on Hygiene and Public Health—Stanley H. Osborn, M.D., Chairman, adopted the following definition of public health:

"'Public Health' is the art and science of maintaining, protecting and improving the health of the people through organized community efforts. It includes those arrangements whereby the community provides medical services for special groups of persons and is concerned with prevention or control of disease, with persons requiring hospitalization to protect the community and with the medically indigent."

NUTRITION FOUNDATION MAKES ADDITIONAL GRANTS

At a recent meeting, the Board of Trustees of the Nutrition Foundation, Inc., New York City, appropriated $185,600 for research in nutrition problems, bringing to a total of $1,810,000 the awards by the Foundation to 62 universities and medical centers in North America.

Charles Glen King, Ph.D., who is the Scientific Director of the Foundation, summarized the advances through basic research made possible by the Foundation in relationship to public health, especially with reference to hypertension, the anemias, dental caries, and protein deficiencies.

FRANCIS AMORY PRIZE IS AWARDED

The American Academy of Arts and Sciences has announced the award of $21,000 which is given every seven years for outstanding work in the alleviation or cure of urological disorders.

The prize was first awarded in 1940. A 1948 award will be equally divided among the following persons:

Dr. A. B. Gutman
Dr. Charles B. Huggins
Dr. W. J. Koff
Dr. G. F. Marian
Dr. G. A. Papanicolaou
Dr. S. A. Waksman

FORD FOUNDATION TO STUDY AREAS OF USEFULNESS

The Ford Foundation, established by Henry and Edsel Ford in 1936, and with present resources of $205,000,000, now has an advisory committee of six to determine the areas of human welfare in which the Foundation can most effectively expend its funds. This committee is being asked to report by midsummer of 1949 so that the foundation may be ready to undertake an active program by 1950.

Committee members and areas they represent are:

Business: Dr. Thomas Carroll, Syracuse University
Education: Dr. Donald G. Marquis, University of Michigan; Dr. Francis T. Spaulding, N. Y. State Education Commissioner
Health: Dr. T. Ducket Jones, Harvard Medical School, and Whitney Foundation, New York
Natural Sciences: Dr. Charles C. Lauritson, California Institute of Technology
Political Science: Dr. Peter Odegard, University of California

The study to be made under the supervision of this committee will be directed by H. Rowan Gaither, Jr., San Francisco attorney and general counsel of the Rand Corporation. He will be assisted by William W. McPeak, formerly with the Information and Research Branch of the War Department, who will be in charge of the committee's New York headquarters, 75 East 56th Street. A second assistant will be Dyke Brown.

The Ford Foundation, whose President is Henry Ford II, is reported to be the largest public trust in the world. It was created as a nonprofit corpora-

tion under Michigan law "to receive and administer funds for scientific, educational and charitable purposes, all for the public welfare."

ADVISORY COMMITTEE IN HEALTH EDUCATION APPOINTED FOR NATIONAL FOUNDATION FOR INFANTILE PARALYSIS

Announcement has recently been made of the appointment by Basil O'Connor, President of the National Foundation for Infantile Paralysis, Inc., New York, of an Advisory Committee to the Health Education Department of the National Foundation. These persons who represent various aspects of education and of health from the administrative, pediatric, and teacher training viewpoints, were called for their first meeting late in 1948.

The group consists of the following persons:

Paul E. Elicker, Sc.D.
Walter Ellsworth Hager, Ph.D.
Alice V. Keliher, Ph.D.
Harry J. Linton, M.A.
Elizabeth A. Lockwood, Dr.P.H.
William Palmer Lucas, M.D.
W. Carson Ryan, D.Ed.
Hugh R. Leavell, M.D.
Lucy S. Morgan, Ph.D.
Arthur S. Steinhaus, Ph.D.

Sally Lucas Jean is consultant in health education for the Foundation. Pauline Brooks Williamson is Chairman of the Foundation's Committee on Proposed Motion Pictures for High School Students.

NATIONAL MALARIA SOCIETY

The National Malaria Society held its 31st annual meeting conjointly with the American Society of Tropical Medicine, the American Academy of Tropical Medicine, and the American Society of Parasitologists in New Orleans, La., December 5–9, 1948. The following officers were elected:

President: Dr. Wendell Gingrich, Galveston, Tex.
President-Elect: Dr. Paul F. Russell, New York, N. Y.
Vice President: Dr. Ernest Carroll Faust, New Orleans, La.
Director: 3 year term, H. W. Van Hovenberg, Mt. Pleasant, Tex.
Editor: Frederick L. Knowles, Memphis, Tenn.

Dr. Martin D. Young, Columbia, S. C., continues as Secretary-Treasurer.

A PREVIEW OF CHILD WELFARE LEGISLATION

Conferences to preview legislation for children in the 81st Congress were held in Washington and New York in November. At all day sessions in each city various interested agencies discussed legislation to be introduced in the 81st Congress as it affects the health and welfare of children. Among the proposed bills discussed were the national school health services bill, national health insurance legislation, school lunch appropriations, the national child research bill, and the Local Public Health Services Bill of 1948. This last, which will be reintroduced in the 81st Congress under the sponsorship of the National Congress of Parents and Teachers, was discussed in behalf of the Association of State and Territorial Health Officers in Washington by John D. Porterfield, M.D., Ohio State Health Officer, and in New York by Haven Emerson, M.D.

These preview conferences were sponsored by the American Parents Committee, 52 Vanderbilt Avenue, New York 17, from which proceedings are available.

ARIZONA STATE HEALTH DEPARTMENT REORGANIZED

The Arizona State Board of Health has reorganized the State Health Department into four major bureaus as follows: Bureau of Administration, Bureau of Preventive Medical Services, Bureau of Local Health Services, and Bureau of Sanitation. Each bureau head will be

responsible directly to the Director of Public Health and will in turn supervise the activities of the various divisions included under each bureau. The Bureau of Local Health Services will include divisions of local health administration and public health nursing, and several consultant services such as nutrition, medical social work, dental health, and mental health. Bureau and division personnel will serve as consultants for the personnel of local health units in the various counties.

RHODE ISLAND PIONEERS IN DENTAL HEALTH

By a coöperative agreement between the State Department of Health and the Rhode Island Hospital, an expanded long-range program of improving the dental health of the state has been undertaken by the hospital's Joseph Samuels Dental Clinic for Children. In this program, all preschool children will be eligible for dental care, priority being on the basis of need for dental care. J. S. Wisan, D.D.S. is in charge of this part of the program.

40TH OKLAHOMA COUNTY WITH LOCAL HEALTH SERVICE

The Garvin (Okla.) Health Department was organized on November 1, thus becoming the 31st full-time local health department in the state and the 40th county to have such service. Presently it is without a medical health officer, but it is currently being served by the Cleveland County Health Officer, O. R. Gregg, M.D., who will then be supervising the health of about 60,000 persons.

STUDY OF VENEREAL DISEASE CONTROL IN MICHIGAN

A study of case finding in venereal disease control is being made under the joint sponsorship of the Michigan Department of Health and the U. S. Public Health Service, with the coöperation of the local health departments of the state. The object is to find out what is wrong with the current methods of case finding. The study is set up so that within 24 hours after a patient with venereal disease has been interviewed at the Michigan Rapid Treatment Center at Ann Arbor or the Social Hygiene Clinic, Detroit, investigation of contacts can begin. Research began November 1 and will continue until June 30, 1949.

FLORIDA ACTS TO PREVENT POLLUTION OF WATER SUPPLIES

The recent Public Health Engineering Conference held in Gainesville, Fla., and sponsored by the Civil Engineering Section of the University of Florida College of Engineering, had as its theme the protection of ground and surface water supplies from pollution by domestic sewage or industrial wastes. More than 180 representatives of official health agencies and other federal, state, and local departments of government, and representatives of industry, consulting engineers, and professional societies attended. One of the specific acts of the Conference was the formation of The State Coordinating Committee on Surface and Underground Water Pollution Prevention and Abatement, with Professor John E. Kiker, Jr., University of Florida, as Chairman.

PHARMACEUTICAL MANUFACTURERS' AWARD

The National Institutes of Health received the American Pharmaceutical Manufacturers' Association 1948 Scientific Award. It was presented by Ernest E. Irons, M.D., President-Elect of the American Medical Association, at a dinner in New York, on December 7. Dr. Rolla E. Dyer, Director of the Institutes, gave the acceptance address. The award was made at an all day and evening session at which new and basic information on major research progress in drug therapy was reported. Previous

awards have been given to the National Research Council, the Rockefeller Institute for Medical Research, and the American Medical Association.

ARMY RESERVE COMMISSIONS FOR INDUSTRIAL HYGIENISTS AND INDUSTRIAL HYGIENE ENGINEERS

The Department of the Army announces the availability of reserve commissions in the Army of the United States to properly trained industrial hygienists and industrial hygiene engineers. The basic commission is First Lieutenant in the Allied Medical Sciences Section, Medical Service Corps, Medical Department Reserve. Higher ranks will depend upon suitable educational and experience qualifications. Further information, from the local Reserve Unit Headquarters in your area, The Adjutant General, Department of the Army, Washington 25, D. C., or from Department of the *Army Circular No. 210,* July 14, 1948.

BORDEN AWARD TO DR. PAPANICOLAOU

George N. Papanicolaou, M.D., Professor of Clinical Anatomy, Cornell University Medical College, has been awarded the 1948 Borden prize for outstanding contribution in the field of medical science by a faculty member of an American medical college. The award, presented at the recent annual meeting of the Association of Medical Colleges was for work in developing tests for early detection of cancer.

FRANCES STERN MEMORIAL SCHOLARSHIPS

On October 17, in Boston, a memorial service was held for Frances Stern whose death occurred in December, 1947. Her chief interest was the Food Clinic at the Boston Dispensary. Because of her efforts, Tufts College has established a new course in nutrition and dietetics which includes the Food Clinic Course at the Boston Dispensary. The course for graduate students leads to a Master's Degree in Education.

Miss Stern's friends as a memorial to her have established a Frances Stern Scholarship Fund, the income from which will be used to help deserving students complete this course of study. Contributions and inquiries should be sent to Frances Stern Scholarship Fund, 25 Bennett St., Boston 11.

HEALTH OFFICER FOR PLACER COUNTY

Placer County, population about 30,000, is the newest California county to have a full-time health officer. He is Saul Ruby, M.D., formerly San Diego County director of communicable diseases.

MEDICAL SCHOOLS TO RECEIVE LARGE FUNDS FOR PSYCHIATRY TRAINING

In accordance with the recommendation of the National Advisory Mental Health Council at a recent meeting in Washington, the Surgeon General of the Public Health Service, Dr. Leonard A. Scheele, has approved the applications of 42 medical schools in the United States to receive federal funds totalling $1,498,333 for developing or expanding training in psychiatry for undergraduate medical students. Funds will be made available for the school year 1949–1950 and will be paid in annual allotments over a three year period.

The program making psychiatric training available to undergraduate medical students was developed as a result of representations by health authorities that all physicians need to be familiar with the effect of the emotions on the general health of the individual, and that all physicians should be trained to recognize the signs of incipient mental disturbances. The importance of early recognition as a part of preventive medicine was stressed by the Surgeon General.

According to Dr. Scheele, the size of each grant was determined by pro-rating

the requirements for the school against the funds appropriated for the purpose under the National Mental Health Act. Funds average about $35,000 as a total grant for three years.

OKLAHOMA PUBLIC HEALTH ASSOCIATION

The Annual Meeting of the Oklahoma Public Health Association was held in the State Capitol Building, Oklahoma City, December 6–8, 1948, under the Presidency of Hardy Watson. The purpose of the Association is "to assist in protecting and promoting public health, to advance the public health program of the State of Oklahoma, and to provide for the enlightenment and scientific advancement of its members through the interchange of ideas and experience."

About 400 persons attended the meetings in which several persons from out of the state participated, including H. F. Kilander, Ph.D., New York; Pearl Shalit, R.N., Washington, D. C.; Roscoe P. Kandle, M.D., Field Director, American Public Health Association, New York; and William T. Ingram, M.P.H., Engineering Field Associate, American Public Health Association, New York.

A constitution and by-laws were adopted looking toward a prospective affiliation of the Oklahoma Public Health Association with the A.P.H.A.

CONNECTICUT PUBLIC HEALTH ASSOCIATION

The fall meeting of the Connecticut Public Health Association was held in Hartford on December 8 with nearly 200 persons in attendance. The program was featured in the morning session with a panel discussion, "What and How To Tell the Public," under the Chairmanship of Nell McKeever, Health Education Consultant, U. S. Public Health Service, and including among the participants a health educator, a health officer, a laboratory technician, a medical social worker, a nutritionist, an office manager, a public health nurse, a sanitarian, and a statistician.

At the luncheon session the speaker was James R. Miller, M.D., Trustee of the American Medical Association, and a delegate to the World Health Organization meeting in Geneva, who spoke on the WHO Assembly.

The afternoon session was notable among other things for a panel discussion on chronic diseases in Connecticut from the public health standpoint. Participants included James C. Hart, M.D., Acting Director of the Bureau of Preventable Diseases, Connecticut State Department of Health; Charles Bingham, M.D., Chief of Medical Service at the Rocky Hill Hospital for Chronic Illness; Alfred L. Burgdorf, M.D., Health Officer of Hartford; Eckka Gordon, Director of Social Service, Grace-New Haven Community Hospital; William Horton, M.D., Medical Director of the State Welfare Department; and Dorothy Peck, R.N., Public Health Nursing Consultant, State Health Department. Other subjects on the program included health aspects of pollution control by Warren Scott of the Department of Sanitary Engineering, and a program proposed for the conservation of hearing in children by Florence A. Browne, M.D., Child Hygiene Physician, State Health Department.

The President of the Connecticut Public Health Association is George B. Davis, M.D., of Norwalk. The Secretary is Muriel Bliss, Ph.D., of Hartford.

U.S.P.H.S. REORGANIZES ENGINEERING ACTIVITIES

As a result of the passage by the 80th Congress of the Water Pollution Control Act, the U. S. Public Health Service has reorganized its engineering activities. The former sanitary engineering division has been replaced by two divisions, on sanitation and on water pollution control, each of which will be under the

supervision of Assistant Surgeon General, Mark D. Hollis, who is the chief sanitary engineering officer of the Service.

The division of sanitation, Sanitary Engineer Director Callis H. Atkins, Chief, now is responsible for all former sanitary engineering division activities except water pollution control and research in environmental sanitation. The division of water pollution control with Sanitary Engineer Director Carl E. Schwob as Chief, will carry out the terms of the Water Pollution Control Act, which provides for financial and technical assistance to the states in the planning and execution of their water pollution control activities. It will also be in general charge of the Environmental Health Center at Cincinnati which is engaged in basic research and investigations in the field of water and sewage treatment, and milk and food sanitation.

WISCONSIN PUBLIC HEALTH CONFERENCE MEETS IN MADISON

The meeting of the Wisconsin Public Health Conference was held December 20–21 in Madison under the sponsorship of the Wisconsin Public Health Council, the Wisconsin Association for Public Health, the University of Wisconsin, and the Wisconsin Board of Health.

Featured at the first session was a symposium on local health units for the state in which outside speakers included Haven Emerson, M.D. of New York, Chairman of the A.P.H.A. Subcommittee on Local Health Units; John W. Ferree, M.D., Associate Director, National Health Council; Roscoe P. Kandle, M.D., Field Director, A.P.H.A.; and Vlado A. Getting, M.D., Massachusetts State Commissioner of Public Health.

At the Conference session on December 21 the Wisconsin Association for Public Health was formally organized. A Constitution and By-Laws were adopted covering the objectives of the Association, "to promote and protect public and personal health."

More than 580 persons were in attendance, including Frank V. Meriwether, M.D., Medical Director, U. S. Public Health Service, Chicago; Charles F. Sutton, M.D., Illinois State Department of Public Health; A. J. Chesley, M.D., State Health Officer of Minnesota; Vernon M. Winkle, M.D., of the State Department of Public Health, Kansas; and C. L. Putnam, M.D. of the Iowa State Department of Health. Other speakers included Basil C. MacLean, M.D., Director of Strong Memorial Hospital, Rochester, N. Y., on "Coordination of Hospitals and Health Departments"; G. D. Cummings, M.D., Director of the Bureau of Laboratories in the Michigan Department of Health on "The Functions of Public Health Laboratories"; Ellis S. Tisdale, Senior Sanitary Engineer, U. S. Public Health Service on "The Functions of a Sanitarian in a Local Health Department"; and Frederick S. McKay, D.D.S. of Colorado Springs on "Fluorine in the Prevention of Dental Decay." Other speakers were Paul H. Stevenson, M.D. of the U. S. Public Health Service, on "Local Public Health Mental Hygiene Activities"; Margaret Taylor, R.N., Director, Public Health Nursing Course, University of Minnesota, on "The Public Health Nurse Rations Her Time," and a panel on "Local Public Health Programs" in which the visitors participated.

A.M.A. AGAIN ENDORSES LOCAL HEALTH UNITS

At the interim session of the House of Delegates of the American Medical Association meeting in St. Louis on December 1, the following resolution was adopted:

WHEREAS, No amount of medical care of persons already sick will substantially reduce the incidence of illness; and

WHEREAS, The traditional position of the

American Medical Association has been one of firm support of public health service, in fact, this constitutes a major element of the ten point national health program of the American Medical Association, and

WHEREAS, Large numbers of local areas and counties in the United States are not now and never have been covered by adequate sanitary and other public health services, and

WHEREAS, The Surgeon General of the U. S. Public Health Service has announced that one of his first major objectives is assistance in development of local health units throughout the nation to meet this fundamental need, and

WHEREAS, The medical profession has now an opportunity to exert constructive leadership in this matter, through the national, constituent state and component county medical societies, Therefore be it

RESOLVED, That the House of Delegates reaffirm its abiding interest in the necessity for the provision of full-time modern public health services at the local and community level, including sanitation and all the services usually considered essential for the preservation of the public health, and be it further

RESOLVED, That the U. S. Public Health Service be commended for, and encouraged in, its efforts for the further development of local health units for these purposes, and be it finally

RESOLVED, That the Board of Trustees be commended for its efforts in furthering full-time local health units and urged to continue actively all proper procedures to the end that local public health service shall become adequate throughout the nation.

DEVELOP SCHEME FOR INTERSTATE CONTROL OF RABIES

Interstate action to check the spread of rabies was initiated by the States of New York, New Jersey, and Pennsylvania in December, 1948, at a conference of officials of the three states, held in New York City. The conference was sponsored by New York's Joint Legislative Committee on Interstate Cooperation, headed by Assemblyman Harold C. Ostertag, and by the Council of State Governments.

Pursuant to a conference recommendation, the three states will coördinate interdepartmental efforts to control rabies, and within the states set up a tri-state continuing committee which will synchronize the rabies control work in the region. New York State has already coördinated its own rabies control program through an Interdepartmental Committee on which representatives of the Departments of Health, Conservation, and Agriculture and Markets serve.

The tri-state action was taken as the result of an epidemic of rabies in central New York State which has continued since 1944, and which affects a number of counties bordering on New Jersey and Pennsylvania.

Noticed first among dogs, the disease is now virtually under control in this species in New York as the result of mass dog vaccination programs. The fox has now replaced the dog as the chief vector. Up to mid-December of 1948, only 23 rabid dogs were reported for upper New York State for the year, but 244 rabid foxes had been recorded. Last year 52 rabid dogs were reported in Upstate New York and 275 rabid foxes.

Cattle are the chief targets of New York's "crazy foxes," the conference was told. Farmers lost 440 cows in 1946 from rabies, 329 in 1947, and 210 in 1948. While these losses appear to be declining, both health and agricultural authorities believe it is due to the fact that the disease is now spreading in areas where dairy herds are more scattered, rather than to subsidence of the disease itself.

Pennsylvania authorities participating in the conference at which the inter-state control program was inaugurated, said that 22 rabid foxes were reported in 1946 in Pennsylvania counties bordering New York's infected areas, but the incidence of the disease has apparently declined since then.

Dr. C. P. Bishop, Director of Pennsylvania's Bureau of Animal Industry, cited the bounty system employed by that state as a possible factor in checking the disease among foxes. He

pointed out that Pennsylvania paid out $158,697 in bounties on predators during the fiscal year ending May 31, 1948, and that the chief predators taken, numbering some 33,000, were foxes.

New Jersey authorities reported no incidence of fox rabies, as yet, but were alerted to the possibility of its appearance when New York authorities pointed out that many cases have been reported in Sullivan County, New York, on the New Jersey border. Dog rabies continues to be the prevalent problem in New Jersey, Dr. J. S. McDaniel of the New Jersey Health Department said, particularly in Mercer, Somerset, Union and Middlesex Counties.

New York State's efforts to check the disease in foxes have taken the form of an intensive trapping program carried on through the State Conservation Department by 27 professional trappers. Trapping has been done in 50 mile square control areas, where the disease has been most prevalent, and some 4,000 foxes have been taken in these areas. A check is now under way to determine whether this method is effectively halting the spread of the disease.

John Wilson, coördinator of the rabies program for the New York State Conservation Department, expressed the belief at the conference that the professional trapping method would prove more effective than the bounty system advocated by many sportsmen, inasmuch as the bounty hunters would not necessarily take foxes from the infected areas and would not trap down to the residual breeding stock as the professional trappers do.

Dr. Alexander Zeissig, veterinary consultant of the New York State Health Department, who has directed the dog vaccination program for that state emphasized the importance of public education and voluntary coöperation in the mass vaccination programs as the most effective methods yet devised for combating rabies. He pointed out that compulsory vaccination programs, where instituted in other states, have not been successful, whereas, under the voluntary methods, correlated with a program of public education, from 70 to 90 per cent of the dogs have been vaccinated in infected areas in New York with a corresponding reduction of canine rabies.

NEW YORK STATE PLANS LARGE MEDICAL AND PUBLIC HEALTH CENTERS

In a recent Report of the Temporary Commission on the Need for a State University, submitted to the Governor and the Legislature of the State of New York by a Committee under the Chairmanship of Owen D. Young, it is stated that the conditions of the times require a broadening of the public provisions for higher education on all fronts. The times also require more effective assurance of equality and of educational opportunities for all qualified youth. In the opinion of the Commission these ends can best be served by a long-range program that would include the establishment of a state university and the establishment of two medical centers by the state, including schools of medicine, dentistry, nursing, and public health, one in up-state New York, and one in the New York City metropolitan area. According to the report, this program may be achieved either by taking over and expanding existing private institutions or by building new ones, or by state aid. In addition, it is proposed that there should be established another state-supported school of veterinary medicine at one of the medical centers, and consideration should be given of financial assistance to private medical schools where a special need exists.

The Commission concludes that New York State uses about one-third more doctors than it educates and that expansion is necessary if New York State contributes its share of the supply of doctors required by the expanding

health needs of the state and the nation. A serious shortage of dentists exists. More than half of the New York students of dentistry attend other state schools, reaching a total of more than 800 dental students per year going out of the state beyond those who come in from other states. It is suggested that provisions be made to supply dental hygienists, dental technicians, and dental assistants.

Facilities for the training of nursing students, of practical nurses, and of veterinarians should be expanded.

"The state has special need for more psychiatrists and public health doctors which can be met by medical centers in which appropriate emphasis is given to each of the health service needs." "Practitioners in the health professions need inservice training in new methods of treatment, as well as consulting service, which can best be provided by medical centers."

Many rural areas, in the opinion of the Commission, are suffering from a shortage of dentists. The entire plan should have as a major objective the preparation of physicians and dentists for the rural areas where the need is most acute.

NEW CANCER FILM AVAILABLE

A new film titled "Cancer: The Problem of Early Diagnosis," which is the first in a series of motion picture films on cancer, will be available for loan or purchase after February 1, according to an announcement made jointly by the co-sponsoring agencies—the American Cancer Society, Inc., New York City, and the National Cancer Institute, U. S. Public Health Service, Bethesda, Md.

This is a 16 millimeter color film with sound, said to have a running time of 30 minutes. It was produced under the direction of Charles S. Cameron, M.D., Medical and Scientific Director of the A.C.S. and Austin V. Diebert, M.D., Chief of the Cancer Control Branch of the National Cancer Institute. A 16 page pamphlet describing the film and suggesting ways to use it has been prepared for program chairmen.

According to the co-sponsors, prints for single showings may be had from state cancer society offices, state health departments, or from Association Film's regional offices located in New York, Dallas, Chicago, and San Francisco. Information about this film and five succeeding films in the proposed series may be obtained from the American Cancer Society, 47 Beaver Street, New York 4, or the National Cancer Institute, Bethesda 14, Md.

PERSONALS

CALLIS H. ATKINS,† Sanitary Engineer, heads the newly created Division of Sanitation of the U. S. Public Health Service. This Division has the responsibilities of the former Sanitary Engineering Division except water pollution control and research in environmental sanitation.

WILL H. AUFRANC, M.D.,* of the staff of the U. S. Public Health Service, who served as Venereal Disease Consultant in the District Office in San Francisco, Calif., became Assistant Chief of the Division of Venereal Diseases, U. S. Public Health Service, Washington, effective December 1, 1948.

ANDRE BAUDE, M.D., who has been on the staff of the State Tuberculosis Sanatorium at Norton, Kans., since 1942, is Acting Director of the Division of Tuberculosis Control, Kansas State Health Department.

AMBROSE P. BELL,† former public health engineer for the Washington, D.C., Health Department, was appointed in November, 1948, to the new executive post of Sanitary Engineer, Louisville-Jefferson County, Kentucky, Board of Health.

CHARLES H. BLANDFORD, M.D.,† formerly Director of the Hardin County Kentucky Health Department, has been appointed Director of the Marion County Health Department, with headquarters at Ocala, Fla.

COL. HERBERT M. BOSCH,* Chief of the section on Environmental Sanitation, Minnesota Department of Health, was decorated by the Netherlands Government as a Commander with Swords in the Order of Orange-Nassau in a ceremony held on December 16, 1948, at the University of Minnesota. The decoration was presented on behalf of his government by the HON. L. C. WILTEN, Minneapolis Consul for the Netherlands.

SARAH H. BOWDITCH, M.D.,† has been named Assistant Director of the Division of Venereal Diseases in the Massachusetts State Department of Health. A graduate of the Harvard School of Public Health, she served during World War II as a lieutenant-colonel in the army medical corps.

LYNN BYRNE is the new business manager for the Divide-McKenzie-Williams Counties Health Department with headquarters in Williston, N. D.

MARY T. COLLINS,† on September 1, 1948, became Secretary of the A.N.A. and N.O.P.H.N. Joint Committee on Nursing in Prepayment Health Plans.

LOUISE G. CAMPBELL,† Special Field Consultant, New York State Committee on Tuberculosis and Public Health, on February 1, became Associate in Health Education of the National Tuberculosis Association, New York City.

DOMENIC CAPONE, S.A. Engr. (R),† is Area Supervisor of A Fly Control Project, U. S. Public Health Service, at the Communicable Disease Center, Phoenix, Ariz., where he will be working in conjunction with the Phoenix City Health Department for the next 5 years.

MADGE L. CROUCH for the past year on the teaching staff of the Methodist Hospital in Brooklyn, N. Y., has become Assistant Director of the Red Cross National Blood Program Nursing Division.

GEORGE A. DAME, M.D.,* Director of the Bureau of Local Health Service, Florida State Board of Health, was elected Chairman of the Section on Public Health, Southern Medical Association, at the meeting held in Miami, Fla., October 25–28.

LT. COL. EDWARD J. DEHNE, M.C.,† recently received a decoration and diploma nominating him an officer in the Order of Leopold II by the Belgian Government, in recognition of his wartime services in the European Theatre as a Public Health Specialist.

MARGARET DILL,† who has been on leave of absence to serve as Acting Director of Public Health Nursing Education for the Louisville-Jefferson County, Kentucky Board of Health for the past 6 months because of the illness of the Director, ELIZABETH GOFORTH, has rejoined the staff of the American National Red Cross, and Miss Goforth has returned to duty.

JAMES A. DOULL,* formerly Chief of the Office of International Health Relations, U. S. Public Health Service, Washington, D. C., became Director of Research at the American Leprosy Foundation (Leonard Wood Memorial) November 1, with headquarters in Washington, D. C. As Director, Dr. Doull will conduct studies on the epidemiology of leprosy.

MAJOR FRED H. DOWNS, JR., MSC,* resigned as Director of the Division of Milk and Dairy Products, Louisiana State Health Department on November 18, to return to extended

* Fellow A.P.H.A.
† Member A.P.H.A.

active duty with the United States Army, assigned as Sanitary Engineer, Office of Surgeon, Headquarters Fourth Army, Fort Sam Houston, Texas.

J. M. GORDON, M.D.,† Director of the Carter County Health Department, Ardmore, Okla., resigned in October to accept a position with the veterans' hospital at Legion, Tex.

JOHN F. HACKLER, M.D.,* former Professor of Preventive Medicine and Public Health at the University of Oklahoma School of Medicine, Norman, was recently named Director of the Muskogee County Health Department, Oklahoma.

WINIFRED HELEN HILLARD, R.N.,† formerly Assistant in School Health Education for the District of Columbia Tuberculosis Association, has joined the New York Tuberculosis and Health Association as Health Education Assistant in the Health Education Division.

BENJAMIN G. HORNING, M.D., M.P.H.,* Director of the Division of Medicine, W. K. Kellogg Foundation, Battle Creek, Mich., left on November 30 for Mexico, Central and South America on a 6 month official trip.

MARGARET D. HOWELL, D.M.D., was appointed Children's Dentist in the Division of Dental Hygiene, Connecticut State Department of Health, effective October 1. She will be concerned primarily with the continued provision of dental care to children in rural areas where there is a current shortage of resident dentists.

PAT KELLEY, former Executive Secretary of the San Francisco Tuberculosis and Health Association, is now Director of the American Social Hygiene Association's Western Regional Office with headquarters at 995 Market Street, San Francisco, and a territory including Arizona, California, Idaho, Montana, Nevada, Oregon, Utah, and Washington.

GLADYS KEYES, who joined the staff of the Contra Costa County Health Department, Calif., in November, 1946, has been appointed as the Director of Public Health Nursing, succeeding EDNA ROBINSON, resigned.

CAROLYN KINGDON,† on November 1, became the first Executive Secretary of the National Foundation for Infantile Paralysis, Honolulu Chapter.

AUBREY MALLACH† of the Health Council of Greater New York, who has been its Associate Director since June, 1947, was recently appointed Executive Director.

CLAYTON B. MATHER, M.D.,† formerly Director of the Monroe County, Michigan, Health Department, was appointed Health Officer of Greenwich, Conn., effective October, 1948.

ALBERT MILZER, PH.D.,† Director of the Department of Bacteriology and Virology of Michael Reese Hospital, Chicago, has recently been awarded a grant of $1,000 by the Committee on Scientific Research of the American Medical Association to conduct a survey of virus and rickettsial diseases in the Chicago area.

HAROLD G. NELSON, M.D., has succeeded C. H. KINNAMAN, M.D., as Director of the Division of Epidemiology, Kansas State Health Department. Dr. Kinnaman will continue in a consultant capacity, and will be directly in charge of special programs.

ARTHUR W. NEWITT, M.D.,* Senior Surgeon of the U. S. Public Health Service, on November 1 became tuberculosis control officer for the State of Michigan having resigned a similar position in Chicago.

JACK O'BRIEN has been appointed Public Health Assistant with the Division of Public Health Laboratories, North Dakota State Health Department, Bismarck.

GEORGE W. PAETH, M.D., has been ap-

pointed as Deputy District Health Officer of the Washington-Yamhill District Health Department in Oregon.

ELNA I. PERKINS* has resigned as health education worker with the New York State Food Commission to accept a teaching post in health education at Springfield (Mass.), College.

KURT POHLEN, PH.D.,* has been appointed Assistant Professor in the Department of Hospital Administration of St. Louis University Graduate School, Mo., where he will teach public health and hospital statistics. He continues also as Director of Research and Statistics of the Catholic Hospital Association of the United States and Canada.

M. ALLEN POND* has been appointed Assistant Chief of Engineering Activities of the U. S. Public Health Service to assist MARK D. HOLLIS,† the Chief Sanitary Engineering Officer, in the administration of programs of the Divisions of Sanitation and Water Pollution Control and the Environmental Health Center at Cincinnati, Ohio.

MILA E. RINDGE, M.D.,† who completed her graduate work in Public Health at Columbia University, New York City, last June, has been appointed epidemiologist in the Bureau of Preventable Diseases of the Massachusetts State Department of Health.

MAURICE A. ROE, M.D.,† has been appointed as Regional Medical Director for Region 8 of the U. S. Public Health Service with headquarters in Dallas, Tex. Dr. Roe succeeds KNOX E. MILLER, M.D., who has been assigned to the Milwaukee City Health Department.

MEFFORD R. RUNYON has been elected Executive Vice-President of the American Cancer Society, New York, N. Y., effective February 1, succeeding DOUGLASS POTEAT, who resigned to return to the legal field. Mr. Runyon was formerly Executive Vice-President and Director of Columbia Records, Inc., and last spring directed the Society's field organizations.

MATHILDA SCHEUER, R.N.,* was recently chosen President of the Pennsylvania State Nurses Association at the annual convention in Pittsburgh.

CARL E. SCHWOB,* Sanitary Engineer of the U. S. Public Health Service, has been made head of the newly-created Division of Water Pollution Control of the Service. The new division is charged with carrying out the Public Health Service water pollution control responsibilities as stated in Public Law 845, enacted by the 80th Congress.

BRIGADIER GENERAL JAMES STEVENS SIMMONS, U.S.A.,* Rtd., Dean of the Harvard School of Public Health, received a "Citation of Merit" on November 6, 1948, from Davidson College, Davidson, N. C., for outstanding contributions in the fields of Preventive Medicine and Public Health. General Simmons received his B.S. degree from Davidson College and the honorary degree D.Sc.

LEONID S. SNEGIREFF, M.D.,† recently Medical Director of the New Jersey Division of the American Cancer Society, now heads the research and teaching project in cancer control at the Harvard School of Public Health in Boston.

MELVILLE A. TAFF, JR.,† has joined the Hawaii Department of Health as Chief of the Bureau of Health Statistics. He has held a similar position with the Louisiana State Health Department for the past 5 years.

RAY E. TRUSELL, M.D.,† formerly New York State Health Department epidemiologist has been appointed full-time Professor of Preventive Medicine

* Fellow A.P.H.A.
† Member A.P.H.A.

and Public Health in the Albany (New York), Medical College.

JOYCE MOORE TURNER, formerly nutritionist with the Queens, New York, Chapter of the American Red Cross, has been appointed Nutrition Consultant of the Harlem Committee, New York Tuberculosis and Health Association.

ANTOINE B. VALOIS, M.D.,† Superintendent of the Division of Vital Statistics of the Montreal Department of Health, was elected Chairman of the Section on Vital Statistics of the Canadian Public Health Association at the annual meeting held in Ottawa, on October 18.

LEROY W. VAN KLEECK, Principal Sanitary Engineer in charge of field supervision of sewage treatment plants for the Connecticut State Department of Health, received the George Bradley Gascoigne plaque and the Charles Alvin Emerson award for meritorious and outstanding service to the Federation, at the 1948 annual convention of the Federation of Sewage Works Associations recently held in Detroit.

HELEN M. VAN METER retired from the Bureau of Maternal and Child Hygiene, Connecticut State Health Department, on November 1, after 25 years as Regional Public Health Nurse.

CARL E. WEIGELE, M.D.,† who has been associated with the New Jersey State Department of Health since 1940, has been made Director of the Bureau of Preventable Diseases. He will also serve as Deputy Director of the Department during the Commissioner's absences.

J. M. WISAN, D.D.S., M.P.H.,* in October, 1948, became Director of the Joseph Samuels Dental Clinic for Children of the Rhode Island Hospital. Most recently Director, Division of Dental Health Education of the American Dental Association, he was formerly Chief of the Division of Dental Health, New Jersey Department of Health. He is co-editor of the Association's Dentistry in Public Health, now in press.

LULU K. WOLF, R.N.,† formerly Professor of Nursing at Vanderbilt University, has joined the faculty of the University of California at Los Angeles as Chairman of the Department of Nursing.

WILMA YORK is now a Local Field Supervisor in the Pacific Coast Office of the Metropolitan Life Insurance Company. Miss York has been with Metropolitan since 1939.

Deaths

CHARLES A. BAILEY, M.D., M.P.H.,† Hospital Consultant, Mississippi Commission on Hospital Care, Jackson, Miss., (Unaffiliated Section).

RICHARD C. BECKETT,† Sanitary Engineer for the Delaware State Board of Health for 25 years, died December 16 (Engineering Section).

GEORGE H. COOMBS, M.D., State Health Director of Maine from 1932 until 1937, died November 20 at the age of 85.

HUGH S. CUMMING, M.D.,* retired Surgeon General of the U. S. Public Health Service, and President of the American Public Health Association for the year 1931, died December 20 (Health Officers Section).

NETTIE DORRIS, M.D.,† of the Illinois State Department of Health, died October 10. She had been a member of the medical staff of the department for 15 years (Health Officers Section).

COLONEL ROBERT D. HARDEN, M.C.,† of Halls Camp, Marathon, Fla., (Health Officers Section).

ARTHUR M. JOHNSON, M.D.,* Up-State Director, State Study of Child Health Services, Rochester, N. Y. (Health Officers Section).

HARVEY P. JONES,† Jones & Henry Con-

sulting Engineers, Toledo, Ohio (Engineering Section).

EUGENE E. LAMOUREUX, M.D.,† Director of the Bureau of Preventable Diseases of the Connecticut State Department of Health, died November 22, at the age of 41 (Epidemology Section).

GERALD MORGAN,† Consultant on Disability, Social Security Board, Washington, D. C., (Unaffiliated Section).

WALTER B. MOUNT, M.D.,† Emeritus Obstetrician, Mountainside Hospital, Montclair, N. J. (Maternal and Child Health Section).

GEORGE H. RAMSEY, M.D., DR.P.H.,* Resident Lecturer in Epidemiology (on leave) Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, (Epidemiology Section).

MICHAEL D. RIORDAN, M.D.,† Health Officer of the towns of Chaplin and Windham, Conn., for 13 years, died October 28 (Health Officers Section).

JOSEPH L. SCHWARTZ, M.D.,† President, TruTest Laboratories, Philadelphia, Pa., (Laboratory Section).

EDGAR E. SHIFFERSTINE, M.D., Chief of Rheumatic Heart Clinics, Pennsylvania Department of Health, died August 22.

BENJAMIN J. SLATER, M.D.,† Associated Medical Director of the Eastman Kodak Company, and former President, New York State Society of Industrial Medicine, died on December 6 (Industrial Hygiene Section).

ALBERT E. SMALL, M.D., M.P.H.,† Chairman, Board of Health, City of Melrose, Mass., (Health Officers Section).

HAROLD A. THOMPSON, M.D.,† City and County Bacteriologist, San Diego, Calif., (Laboratory Section).

WILLIAM C. TREDER, M.D.,† Commissioner of Health, Schenectady, N. Y., (Health Officers Section).

ORPHA L. WHITE,† Executive Secretary of the Lake County (Illinois) Tuberculosis Association since 1937, died November 14 (Public Health Education Section).

BYRON W. WOOD, M.D.,† Director, City Health Unit, Port Arthur, Tex., (Health Officers Section).

Despite rigid precautions taken *before* delivery, milk is too often contaminated by the ultimate buyer—especially in public places.

Fork-prying and finger-pushing methods of opening bottles may easily result in pollution. And once conventional outer hoods have been carelessly discarded, pouring lips are highly susceptible to hand- and air-borne germs.

Seal-Kap minimizes these two dangers. Seal-Kap is removed readily—no prying with finger or fork. The milk need be exposed to the air only while being poured. Then Seal-Kap snaps back on, as often as necessary, to cover the pouring surface for snug, last-drop protection — protection that requires little *effort from the user.*

Seal-Kap's single-operation sealing and capping also makes it economically advantageous for dairies to offer the public this post-delivery safeguard to health.

35 YEAR INDEX

OF

American Journal of Public Health

Volumes 1 to 35 for the Years 1911 to 1945

All of the literature published on a given subject in the Journal during the years 1911 through 1945 will be found in one place. A complete Author's index is also included. The *Index* makes available a vast storehouse of valuable information contained in the fifty thousand pages published during this period. The tremendous task of preparing the *Index* was done by Louise Pickens. Tanner, Ph.D., and Fred W. Tanner, Ph.D.

DIAGNOSTIC PROCEDURES IN VIRUS AND RICKETTSIAL DISEASES

This handbook, prepared by the Committee on Virus and Rickettsial Diseases of the Laboratory Section and edited by the Chairman of the Committee, Thomas F. Francis, Jr., M.D., details procedures which can be employed and interpreted by laboratory workers in the diagnosis of sixteen virus diseases. The diseases selected are essentially those of man for which procedures are available for use in a diagnostic laboratory.

Each of the sixteen sections has been written by an authority in the field. Much of the experience of each author has been contributed to his chapter and as a result the entire volume constitutes a compilation of methods proved by actual experience.

The volume has grown out of a recognized need for a publication of collected methods and has developed from a round table presentation at the Annual Meeting of the American Public Health Association in 1946. The methods are not presented as standards but are those most currently useful.

Members of the committee who have contributed and their subjects are as follows:

Psittacosis
K. F. Meyer, Ph.D., M.D. and B. Eddie, Dr.P.H.

Lymphogranuloma Venereum
Geoffrey Rake, M.B.

Trachoma and Inclusion Blennorrhea
Phillips Thygeson, M.D.

The "Shattuck Report"

Republished for the first time!

Report of the Sanitary Commission of Massachusetts: 1850

By Lemuel Shattuck and Others

THIS is the famous first general plan for the promotion of public health to be presented to an American governmental body, and its influence over the whole field ever since that time can hardly be exaggerated. The "Shattuck Report" made fifty specific recommendations regarding sanitation, recording of vital statistics, protection of school children, medical research, nurses' training, slum clearance, and other problems vital to the increase of the mean expectation of life in the United States. Its first proposal was for the creation of state and local boards of health in an era when such state commissions were non-existent.

Lemuel Shattuck (1793–1859) was a business man—a bookseller and publisher—whose important public services include plans for the recording and preservation of public documents, and the establishment (due to his efforts) of the Massachusetts System for the registration of births, deaths, and marriages. In 1839 he was one of the founders of the American Statistical Association.

Now republished for the first time since its original release in 1850, this facsimile edition of the "Shattuck Report" again makes it available to everyone interested in medicine, public health, or the vital statistics and social conditions of the mid-nineteenth century. It is sponsored by the American Public Health Association, the Massachusetts Public Health Association, the Harvard Graduate School of Public Health, the Massachusetts Department of Public Health, and the Boston Health Department. *ix + 321 pages, $4.50*

The Abundant Nutrient Values of MEAT

KIND OF MEAT	COMPLETE PROTEIN	B VITAMINS			FOOD IRON
		THIAMINE (B_1)	RIBOFLAVIN (B_2)	NIACIN	
 PORK	EXCELLENT	EXCELLENT	FAIR	EXCELLENT	EXCELLENT
 BEEF	EXCELLENT	FAIR	EXCELLENT	EXCELLENT	EXCELLENT
 LAMB	EXCELLENT	FAIR	GOOD	EXCELLENT	EXCELLENT
 VEAL	EXCELLENT	GOOD	GOOD	EXCELLENT	EXCELLENT
 VARIETY MEATS (LIVER, HEART, KIDNEY)	EXCELLENT	EXCELLENT	EXCELLENT	EXCELLENT	EXCELLENT
 SAUSAGE (FRANKFURTERS, BOLOGNA)	EXCELLENT	GOOD	GOOD	GOOD	EXCELLENT

ALL VALUES ARE BASED ON COOKED MEATS . . . MEAT ALSO SUPPLIES SIGNIFICANT AMOUNTS OF COPPER AND PHOSPHORUS

While its high content of biologically complete protein ranks meat among man's best protein sources, its contribution of many more indispensable nutrients further enhances its over-all desirability in the daily dietary.

As is readily seen in the chart above, every kind of meat is an excellent source of high quality protein and of iron. Meat further supplies significant amounts of the three B complex vitamins, thiamine, riboflavin and niacin. Certain cuts and kinds of meat are, as a matter of fact, among our richest food sources of thiamine and niacin. All meat, regardless of grade or cut, makes these contributions.

Due to the excellent digestibility of meat—from 96 to 98 per cent—the metabolic availability of its protein and other nutrients is virtually assured, making it particularly valuable in many disease conditions in which these nutrients are especially needed.

DIFCO

Isolation and Cultivation of BRUCELLA

Preliminary Enrichment

Isolation of Brucella strains from blood specimens is best accomplished by preliminary enrichment of the sample in medium prepared from Bacto-Tryptose Broth. For isolation from samples of infected milk no enrichment is required.

Isolation of Strains

After enrichment the blood specimens are streaked on plates of Bacto-Tryptose Agar and the plates are incubated at 37 ° C., milk samples are streaked on plates of Bacto-Tryptose Agar prepared with crystal violet to inhibit the streptococci and other Gram-positive organisms.

Differentiation of Types

Bacto-Tryptose Agar to which thionin or basic fuchsin has been added is recommended for the differentiation of newly isolated strains of Brucella.

Mass Cultivation

Bacto-Tryptose Agar, prepared without addition of dyes or other ingredients, supports luxuriant growth of all Brucella. It is an excellent medium for mass cultivation of the organisms for preparation of bacterial vaccines or antigens.

Routine for discovery

The national total of undiagnosed or "unknown" diabetics may run from a million to two or even three.[1,2] Modern treatment, when promptly initiated, can do much to prevent metabolic decompensation and to minimize diabetic complications. Therefore, the clinical revealment of diabetes mellitus at an early stage is essential.

Thus, "all patients who present themselves to the physician for an examination should have a routine urine examination."[3] In this phase of practice, the advantages of *Clinitest*® tablets for urine-sugar analysis are considerable.

Clinitest is dependably accurate, yet it takes only a few seconds to perform. The test is simple—no external heat need be applied; interpretation is by direct color comparison. *Clinitest* is convenient both for the doctor's office routine and for the diabetic patient's prescribed sugar-level checkups.

STUDIES IN PSYCHOSOMATIC MEDICINE

FRANZ ALEXANDER and THOMAS M. FRENCH, et al. *Chicago Institute for Psychoanalysis.* Comprehensive information on the new era of medicine called "psychosomatic", in a collection of papers based on the psychoanalytic study of patients suffering from chronic disturbances such as peptic ulcer, bronchial asthma, acute laryngitis, hay fever, eczema, migraine, and others. Written during the past 16 years by the Staff of the Chicago Institute for Psychoanalysis, they present a method of approach to the study of disease that utilizes all available sources of information—the observation of behavior, verbal communications, and bodily symptoms. The papers are classified according to type of somatic disturbance. *"Contains many . . . simply stated truths in the field of psychosomatic medicine. . . . An important addition."*—Dr. Frank G. Slaughter, N. Y. Times. *568 pages.* $7.50

MICROBES MILITANT

A Challenge to Man

FREDERICK EBERSON. *Kennedy Veterans Hospital.* May we expect some day to conquer wholly the unfriendly microbes? This significant, informative report considers the question in the light of the microbe's challenging ability to evolve and adopt new kinds of resistance when threatened. It reviews the whole new field of microbiology . . . highlights the dramatic history of preventive medicine from Koch and Pasteur to the present. The new antibiotics—heralds of a new age—and recent fruitful researches in the fields of viral and rickettsial diseases are fully covered. Truly expert treatment of a subject especially vital in these days of global travel and possible bacteriological warfare. *A revision. Ill. 401 pages.* $4.50

HIDDEN HUNGER

I. G. MACY and HAROLD H. WILLIAMS. *Children's Fund of Michigan.* Presenting the broad aspects of nutrition, this volume discusses the food situation as it has developed since 1930 . . . analyzes food habits, fads, fashions and their effects; symptoms and consequences of nutritional deficiencies; conservation of food nutriments in cooking and processing of food; new developments for improving dietary balance, and many other important topics. *Ill. 26 tables.* $3.00

INTRODUCTION TO CLINICAL PSYCHOLOGY

L. A. PENNINGTON, *University of Illinois,* and IRWIN A. BERG. *Northwestern University.* 23 Contributing Specialists. This book offers a broad acquaintance with the behavior problems encountered by clinicians—whether in industry, the hospital, community clinic or university counseling center—and with the techniques used by qualified practitioners today. It clarifies the relationship of clinical work to the psychiatric profession and points out areas in which the clinical psychologist, the psychiatrist, and the case worker can be of mutual assistance. *595 pages.* $5.00

THE DIABETIC'S HANDBOOK

ANTHONY SINDONI, Jr., *Philadelphia General and St. Joseph's Hospitals.* 6 Contributing Specialists. This new manual explains in simple, nontechnical terms the things diabetics must know and do to cooperate fully in their treatment. Special set of almost 200 Questions-and-Answers cover every pertinent question patients ask about their part in the care of the disease. Suggestions are offered for making dieting easier and the diabetic's regimen more manageable. Many tables, menus, recipes, charts, illustrations. $3.00

THE MONEY VALUE OF A MAN

LOUIS I. DUBLIN and ALFRED J. LOTKA, *Metropolitan Life Insurance Co.* For health officers and social workers interested in the costliness of disease and premature death, here are authoritative computations of the money values of persons at various ages according to their earnings. Tables have been reworked extensively to conform to altered conditions, notably the increased life expectation of the American population. Book discusses the family, the cost of raising a child, the burden of the handicapped, and many other important points. *8 charts. 57 tables.* $6.00

Modify Measles—

with Immune Serum Globulin —Cutter

Help build natural immunity—simultaneously!

Measles is climbing to its peak right *now* according to U. S. Public Health reports. An important consideration for your small, red-rashed patients is modification with Immune Serum Globulin—Human to help build a natural immunity and reduce the danger of measles—resultant complications.

Now is a good time to use Cutter Immune Serum Globulin fractionated from human *venous* blood. 160 mgm. per cc.—this known constant gamma globulin content permits low volume, adjustable dosage.

Keep your pharmacist advised of your needs for gamma globulin—and specify Cutter.

IT'S THE GAMMA GLOBULIN THAT COUNTS IN CUTTER

	Blood Source	Solution Appearance	Gamma Globulin Content	Modification Dosage
Cutter Immune Serum Globulin-Human*	Fresh Normal VENOUS Blood	Water Clear Hemolysis-Free	160 mgm. Per cc.	0.3 — 0.4 cc.

Human* means venous blood, freshly pooled from normal healthy donors.

Water Clear Solution, hemolysis-free and non-pyrogenic.

Gamma Globulin concentration—160 mgm. per cc.—reduces dosage volume with constant globulin potency—adjustable for prevention or modification of measles.

BROWN Blood Grouping and Cross Matching BOARD

- Minimizes the possibility of technical or clerical errors.
- Embodies all the latest approved technics of blood grouping, Rh typing, Rh sensitivity testing and cross matching for transfusion.
- Simplifies and combines these technics in an orderly sequence.
- Facilitates the grouping and cross matching of blood for emergency or routine use.
- Can be used for routine Rh typing and sensitivity testing in individual maternity cases.

The Brown Board[1] was developed in the Duke University Hospital Blood Bank to increase efficiency and reduce errors in blood typing and cross matching. It consists of an etched and stamped metal plate on a hardwood base, with an Rh typing box, anti-serum bottle adapters, reagent bottles, test tubes, dropping pipettes and concavity slides for Rh typing.

Tubes and reagent bottles have in-the-glass labels in different colors, matching the labelling and coloring of their places in the board. Each reagent bottle and cross matching tube is of a different shape and size, so that it fits only in its proper place. Anti-serum bottle adapters hold any commercial anti-serum bottle; they are permanently marked, fit only in their own place in the Board and are colored to conform to the coloring recommended for the sera by the National Institute of Health. Reagent bottles and adapters are designed to permit one-hand removal and replacement of the dropping pipettes.

The Rh typing box[2] is lighted, tiltable and designed to maintain a temperature of 37° to 42° C in the slide concavity where the blood sample is placed.

The Board has a slot to hold the Donor Card and Transfusion Request Form directly in front of the technician while tests are being made. A blotting paper holder is also provided, conveniently near the technician.

1. "A Note on Blood Grouping and Cross Matching with Special Reference to a Convenient Cross Matching Board." Brown, I. W., Jr., M.D. In press.
2. "The Demonstration of Anti-Rh Agglutinins—An Accurate and Rapid Slide Test," Louis K. Diamond, M.D., Boston, Mass., and Neva M. Abelson, M.D., Philadelphia, Pa., Jl. of Laboratory and Clinical Medicine, Vol. 30, No. 3, March 1945.

A-2800 Brown Blood Board, complete with Rh typing box, anti-serum bottle adapters, reagent bottles, test tubes, dropping pipettes and four-concavity slides. Each $90.00

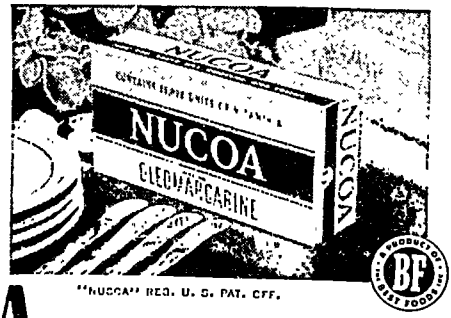
Twins—BUT NOT IDENTICAL!

The twin boys in above photograph—Marc and Clay Cavness of Phoenix, Arizona—neither look exactly alike, nor are they duplicates in characteristics.

This is true of margarines also. The more you know about margarine through use on your own table, the more you realize that all brands cannot be lumped in one category. *Good* margarine is not easy to make.



Why Nucoa is the margarine mothers by the million choose

Mrs. Jack C. Cavness, the twins' mother, is typical of the millions of high-minded young American mothers who let Nucoa margarine help them solve the problem of providing appetizing, nutritious meals at moderate cost. Mothers have *confidence* in Nucoa, for Nucoa has been top-quality margarine for over thirty years. Its makers pioneered, one by one, the important improvements that won approval for margarine from dietary experts. Nucoa was the first all-*vegetable*-oil margarine . . . the first made with vegetable oils from crops grown only within Continental United States . . . the first to add Vitamin A . . . the first to step up Vitamin A fortification to 15,000 U.S.P. units per pound, *guaranteed.*

Pound after delicious pound—always the same

Not only is Nucoa's food value as calculated as baby's first formula, but the *uniformity* of Nucoa in pleasing texture and delicious flavor is controlled by manufacturing skill and rigid testing—54 laboratory tests daily on the oil alone. And Nucoa always tastes sweet and fresh. Nucoa is freshly made the year round, on order only. There is no "storage" Nucoa!

Make your own appraisal of Nucoa—enjoy it on your own table.

SECURITY
. . . at a saving

Forms an *air-tight* seal

Covers the pouring lip of the bottle

Eliminates seepage

Does away with "cap seal"

Makes a perfect re-seal

When bottled milk is capped with Dacro P-38 it is *securely sealed* against a wide variety of hazards that can easily affect milk purity. Both the Steel Dacro P-38 and Aluminum Dacro P-38 give this dependable protection . . . and at a saving. Dacro P-38 saves on cap cost because of its smaller size. But even more important are the economies it offers the dairy plant operator through the proven efficiencies of the Dacro Capping System.

Recognized FOR ITS UNUSUAL MERIT

KWELL®
OINTMENT

THE outstanding scabicidal and pediculicidal properties of Kwell Ointment were again reaffirmed in a recently reported study. Cannon and McRae[1] treated 100 cases of scabies and achieved clinical cures in all patients. Sixty-one patients required but one application, 36, two applications, and the remaining 3, three applications. Subjective relief was apparent in 2 to 3 hours in a few patients, and was complete in 24 to 48 hours in half the patients. No instance of dermatitis was observed, and no evidence of sensitivity was obtained on subsequent testing. Kwell Ointment was applied in the presence of secondary infection without adverse results; in fact, control of the infestation permitted prompt healing of the superimposed dermatitis. Equally good results were obtained in a small series of pediculosis corporis and pubis.

This outstanding performance of Kwell Ointment has been previously reported.[2,3] Its sound clinical and experimental background merit its use whenever a diagnosis of scabies or pediculosis is made.

Kwell Ointment containing 0.5 per cent of the gamma isomer of 1, 2, 3, 4, 5, 6,-hexachlorocyclohexane is available on prescription in 2 ounce and 1 pound jars. Literature to physicians on request.

A New Aid to Public Health

by

"LAWRENCE"

NEW 700 POUND "AERO-MIST" SPRAYER IDEAL FOR MUNICIPAL INSECT CONTROL PROGRAMS

In addition to its famous L-80 heavy duty mist sprayer "LAWRENCE" now offers in a smaller sprayer, ALL of the exclusive and scientific features, which have made "LAWRENCE" the name to remember in mist sprayers.

Efficient, compact, and economical, the L-40 LAWRENCE AERO-MIST SPRAYER is especially suitable for municipalities where the program is not large enough for the L-80 heavy duty mist sprayer, or for health departments desiring equipment for their own use apart from other municipal operations.

Here is the newest advance in the control of annoying and dangerous insect pests.

Hard-to-get-at spraying areas can be covered easily, quickly, and thoroughly with the L-40 mounted on a small truck or trailer. Like the heavy-duty unit, the L-40 can operate in a 360° circle and on any plane, automatically eliminating blind spots.

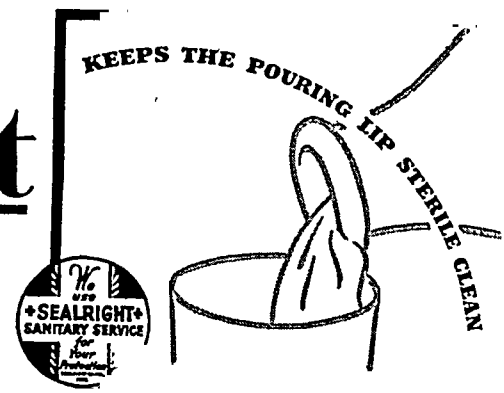
(with apologies to Tennyson)

If there is one place on a milk bottle which should never be promiscuously handled—that place is the pouring surface.

The reason is obvious.

Every drop of milk in the bottle must pass over that pouring surface before it can be used.

No wonder health authorities and public spirited dairies are so insistent upon *sealed* protection of that pouring surface from dairy to home.



In every state and in many foreign countries, Sealright Sealon Hoods are keeping milk bottles safe against contact with hands, melting ice, rain, snow or dusty air. *They protect all the way to the home.*

In the Hustle and Bustle

A MEAL IS LOST

THE few minutes saved by skipping breakfast, or eating a skimpy breakfast, may be more costly than generally realized. The student loses in power to concentrate, the worker in acuity, the housewife in stamina. Yet a surprisingly large segment of our population is guilty of this sin of omission.

In the aim to provide one-fourth to one-third of the daily caloric and nutrient needs in the morning meal, breakfast can be planned profitably around a widely endorsed basic breakfast pattern. Consisting of fruit or fruit juice, breakfast cereal, milk, bread and butter, this meal provides well balanced nutrient composition, economy, and almost endless variety. Its nutrient contribution, and that of the cereal serving, consisting of cereal, milk, and sugar, are outlined in the tables.

The presence of this seal indicates that all nutritional statements in this advertisement have been found acceptable by the Council on Foods and Nutrition of the American Medical Association.

How mild can a cigarette be?

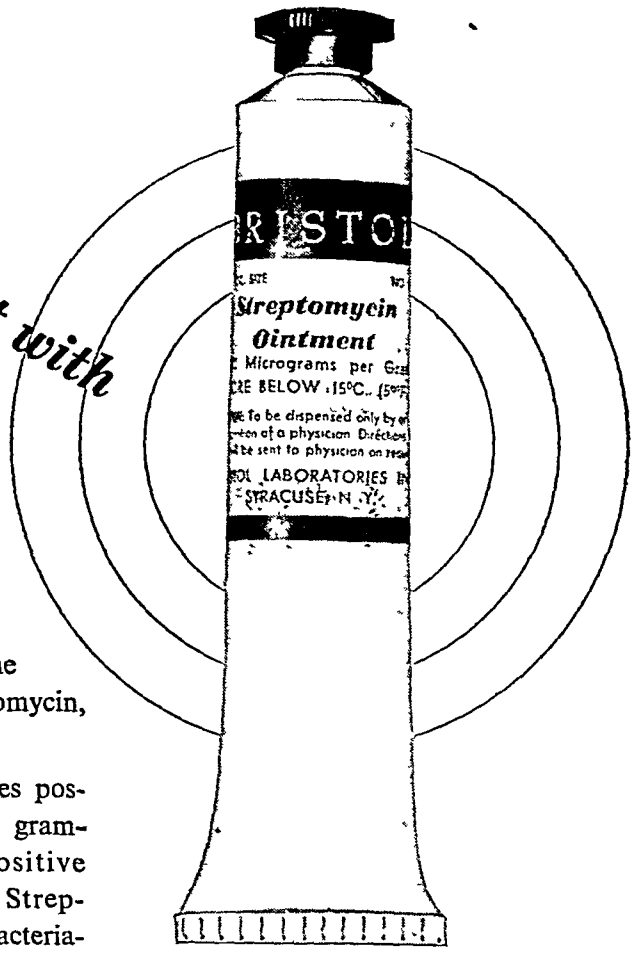
In a recent coast-to-coast test, hundreds of men and women smoked Camels — and only Camels — for 30 consecutive days. These people smoked on the average of one to two packages of Camels a day during the entire test period. Each week, throat specialists examined these Camel smokers. A total of 2,470 careful examinations were made by these doctors. After studying the results of the weekly examinations, these throat specialists reported:

"NOT ONE SINGLE CASE OF THROAT IRRITATION DUE TO SMOKING CAMELS!"

Money-Back Guarantee!

Test Camel mildness for yourself in your own "T-Zone." T for taste, T for throat. If, at any time, you are not convinced that Camels are the mildest cigarette you've ever smoked, return the package with the unused Camels and we will refund its full purchase price, plus postage. *(Signed)* R. J. Reynolds Tobacco Company, Winston-Salem, North Carolina.

According to a recent Nationwide survey:



MORE DOCTORS SMOKE CAMELS

than any other cigarette

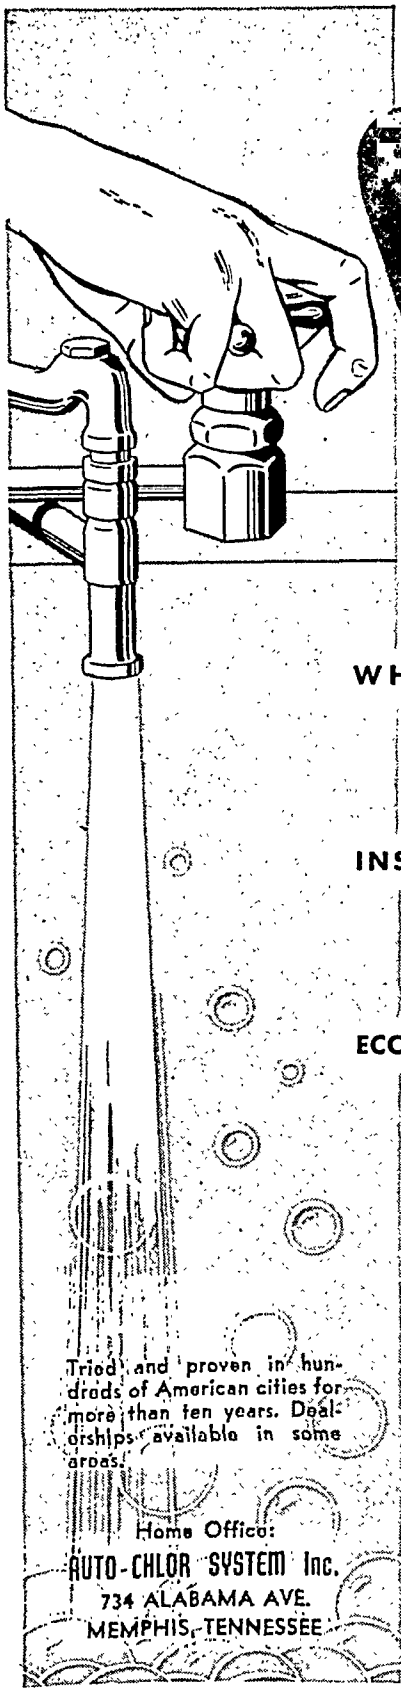
Doctors smoke for pleasure, too! And when

Hit the Whole Target with

When attacking skin and wound infections, more than half of which "will be found to be due to a mixture of organisms",[1] the effective agent is one which, like streptomycin, has a wide antibacterial effect.

BRISTOL STREPTOMYCIN OINTMENT makes possible potent local action against most gram-negative and many common gram-positive organisms (such as Staphylococci and Streptococci). Its bacteria-destructive and bacteria-inhibitory effect is broader than other topical antibiotics. It is, therefore, effective against more skin and surface wound infections.

BRISTOL STREPTOMYCIN OINTMENT, demonstrably less sensitizing than other antibiotics used topically, may be employed with little fear of local reaction. Adverse systemic effects have not been seen following its use.



BRISTOL STREPTOMYCIN OINTMENT is indicated for the treatment of wound and skin infections due to organisms sensitive to streptomycin. Incorporated in a smooth water-soluble base, it is convenient and pleasant to use.

A *NEW effective* treatment for Scabies

No longer are slow, greasy ointments with their attendant messiness necessary to treat scabies. In their stead has come quick, easily applied, highly parasiticidal benzyl benzoate emulsion. • • • Writes Mackenzie[1]: "The ease and speed with which the application can be carried out...rapidity of cure, and the almost immediate relief from itching combine to make it a satisfactory remedy from both the clinical and the public health aspects."

'WELLCOME' **BENZYL BENZOATE** EMULSION 50%

Application: Following a thorough soap and water bath, the emulsion (diluted to 25%) is painted on the entire body, allowed to dry, and then reapplied. A warm bath, 24 hours later, completes the treatment.

Bottles of 4 fl. oz. and ½ gal.

Anniversary Program—150th Year U. S. Public Health Service

The Past and Future of the Public Health Service *

LEONARD A. SCHEELE, M.D., F.A.P.H.A.
Surgeon General, U. S. Public Health Service, Washington, D. C.

THIS morning, 17,000 men and women of the Public Health Service turn their thoughts to this platform. From 44 of the 48 states, from Alaska, the Canal Zone, Hawaii, Puerto Rico, and the Virgin Islands, from headquarters in Washington, and from 14 foreign countries, we salute the American Public Health Association. And we say: "Thank you for honoring us in this special program to commemorate the 150th anniversary of the Public Health Service."

All of us feel that the Health Officers Section has provided an unusually fitting climax to our sesquicentennial. No professional society, no voluntary agency, is so closely related to the Public Health Service as the American Public Health Association. The two organizations are indeed blood relations, for each has fed the life-stream of the other since 1872 when the Association was organized with an officer of the Marine Hospital Service among its ten founders. Eight Presidents of the Association have been Public Health Service officers at the time they held office. Several others have been Service officers at some time in their careers.

As this memorable year draws to a close, then, the Public Health Service feels a special pride in being able to come before the Association with our storied past and our renewed faith in the future.

Coincidence places this commemorative meeting in a perfect setting. Boston is both the cradle of the Public Health Service and the birthplace of the modern public health movement in the United States. Here, in 1799, the first U. S. Marine Hospital opened its doors to sick and injured seamen. Here, too, in 1845, and again in 1850, Lemuel Shattuck wrote his classic reports which became the blueprint for American health organization.

The origins, growth, and development of the Public Health Service are well known, in broad outline, to most of this audience. This is fortunate, because a little mental arithmetic tells me that the time at my disposal allows about 40

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

seconds for each decade of our 150 years, and a few minutes for a look at the limitless future. Such a superficial account would not be satisfying either to the speaker or the audience, so I shall proceed quickly to the future.

First, let us look at our organization as it is today. Our financial situation—I will say this with Yankee caution—is "tol'able." In 1948, appropriations to the Public Health Service, including contract authorizations for construction, totalled over $200 million, and for this fiscal year, 1949, over $275 million. We have three new programs which are not covered by the 1949 budget: the National Heart Institute, the Dental Research Institute, and the program for water pollution control. We await the meeting of the new Congress for full activation of these programs. So I say our situation is "tol'able." Our 1948 and 1949 budgets, however, represent increases upward of 2,000 per cent over appropriations available 15 years ago.

In 1917, the Public Health Service had only 187 commissioned officers, all physicians, and less than 2,000 other employees. In 1940, the combined force included about 8,500 persons. Today, the total, full-time staff of the Service numbers 17,000, of whom 2,000 are officers in the regular and active reserve corps, now including physicians, dentists, engineers, sanitarians, pharmacists, nurses, and dieticians.

The programs of the Service are in three major categories: research, clinical medicine, and public health administration. Three major administrative units complement those categories: the National Institutes of Health, the Bureau of Medical Services, and the Bureau of State Services. The Office of the Surgeon General is presently a fourth bureau, composed of a few unrelated divisions and of the internal management services, such as budget and fiscal, personnel administration, and supply procurement.

Here is a point at which we can take a look at the future. One of my first concerns as Surgeon General is to improve the efficiency of the Public Health Service. The expanding magnitude of our responsibilities demands it.

Six months ago, I appointed a Committee on Organization, composed of members of my staff,* to make a comprehensive study of the organizational structure and working relationships of the Public Health Service, at headquarters and in the field. The committee, under the chairmanship of Deputy Surgeon General W. Palmer Dearing, has worked throughout the summer with the help of many other members of the Service in the various bureaus. They have come up with a series of initial reports which I regard as statesmanlike—reports dealing with general principles of organization and with the committee's first area of inquiry—federal-state activities.

COÖRDINATION OF SERVICES

It is too early to report here the outcome of the committee's specific recommendations. But I can tell you that already the Public Health Service is moving *away* from a categorical approach in all of its activities, and *toward* a more generalized and unified approach.

That trend will be accelerated in the immediate future, and its scope will be broadened. In research, clinical practice, and public health administration, we cannot—and do not—deny the vital importance of specialization. But we do—and we must—abhor the isolation of special knowledge, skills, and services in water-tight compartments.

The end result of isolation can only

---

* Public Health Service Committee on Organization: W. Palmer Dearing, Deputy Surgeon General, Chairman; Harry G. Hanson, Executive Officer, Secretary; J. W. Mountin, Assistant Surgeon General, Bureau of State Services; Mark D. Hollis, Assistant Surgeon General, Sanitary Engineering; R. W. Bunch, Administrative Officer, Bureau of Medical Services; A. F. Siepert, Executive Officer, National Institutes of Health.

be stultifying, whether it occurs horizontally across the three major types of activity, or vertically through the scientific disciplines, the medical specialties, or the categorical health programs. The scope and depth of human knowledge; the infinite variety of special technics are such that no one mind, nor group of minds, can encompass them.

But recognition of this fundamental truth is not enough. It is easy to philosophize and say that all the disciplines and services related to the health of mankind are interdependent. Somewhere, sometime, a start must be made toward an interdisciplinary, integrated approach in all agencies responsible to society for the study and health care of the people.

The Public Health Service, then, is putting its house in order so that we may use fully and more effectively the increased resources provided by Congress for the health of the people. Needless to say, we shall act within the framework defined by the Congress; but we shall seek legislation to authorize any basic changes which we believe to be necessary for efficient administration.

This does not mean a lessened interest in the pioneer work that must be done against the major health problems of our times. Quite the reverse; our plans are to strengthen and sharpen the attack already begun against such massive problems as heart disease, cancer, and mental disease. Other specific problems of the times also await attention. Our interest is in perfecting the Public Health Service administrative machinery through which the objectives of all our programs are reached.

Simply, what we are aiming toward, is to make of our large, sprawling organization a hard-driving, united team. The Public Health Service has grown, programs and separate units have multiplied so rapidly in the past 10 years that there has not been time to prevent a somewhat unbalanced development.

We believe that the collaborating team is the best instrument for the pursuit of knowledge and the provision of health services. Because this is our belief and because we hope to see it adopted throughout the whole structure of research, clinical practice, and public health administration in the United States, we must, perforce, heed those simple words of advice: "Physician, heal thyself." This we propose to do.

LOCAL HEALTH SERVICES

There is one motivating force behind the plans and hopes of the Public Health Service which transcends all special interests. It is a dream that dawned in the minds and hearts of public health workers about 40 years ago. That dream: a local health unit for every community in the United States.

There are men in this audience (some of them members of the Public Health Service) who have fought for that dream all those years, or throughout their professional lifetime. Many men have died without seeing this, their dream, come true. The vision and faith of these men have fertilized the entire field of organized health work for nearly two generations.

"Public health is indivisible," they have said. When the Social Security Act was passed in 1935, providing specifically for the development of local health services—but not for particular disease categories—those men thought the battle was at least half won. The Public Health Service, with its colleagues from the states and territories, supported these principles: Grants-in-aid should be general; the budget structure should be simple; there should be reasonable latitude for administrative discretion in the use of funds appropriated for public health work.

Since that time, the proponents of a generalized health program and full-time local health service have been

somewhat like the salmon—swimming upstream against the strong current of categorical appropriations and programs. They have kept on swimming. The goal is nearer, but it is still far off. That is to say, less than 5 per cent of the American people have fully staffed, well qualified, well supported health services. Although the goal is far from accomplishment, it must not remain far off in time.

Within the next year, an effective plan for insuring complete coverage with local health units must be put into operation. I am convinced that unless definite action is taken by state and local governments to increase organized health services to the people, we shall not be able to advance against the major causes of death and disability in the United States.

Public health work, indeed, seems to have arrived at the still center of human need. If it does not now adapt to contemporary needs, the hurricane of needless death and disease will sweep off in new directions, unchecked by the preventive methods which dynamic, coordinated health services could apply.

We already have evidence that the categorical programs themselves are still far from attaining their objectives, despite the money and effort devoted to them. The reason seems clear. In too many parts of the country, there is no qualified organization to bring the new, special services continuously and effectively, to the people. Even where all the health programs are unified administratively in the local health department, budgetary complications and conflicting lines of authority frequently hamper economical use of funds. These restrictions are even more seriously reflected in the quality of the service rendered to the public.

Additional legislation will be required to insure adequate federal support for local health units. There is a ceiling on Public Health Service appropriations for general grants-in-aid to the states. There are no cealings on such specialized programs as tuberculosis, venereal disease, and cancer control. But it may be that Congress, in the future, will take as a criterion for both general and special grants, the extent to which the states have organized and supported local health units in their jurisdiction.

The Congress and the federal agencies may well say to the states and communities: "It is your move." State aid to local jurisdictions falls far short of the needs. Many communities, on the other hand, do not take advantage of state laws and state aid already at their disposal. State aid to communities should be on the same basis on which federal aid is given to the states —that is, high quality consultative and technical assistance, liberal grants with wide administrative latitude for the local jurisdiction, and requirements for local participation, however small.

The Public Health Service will continue to demonstrate and stimulate expanded health services. We will request that the ceiling on grants for general health programs be removed. And we will support legislation for local health units if it is introduced in the next Congress, and if such action is in accord with the President's policy. In this entire effort, we have the full support of the Federal Security Administrator and our colleagues in the agency.

Last spring, I appeared before a Congressional committee in support of a bill for aid to local health units. Among the few civic organizations supporting the bill, the National Congress of Parents and Teachers bore the brunt of the battle. The State and Territorial Health Officers Association, the American Public Health Association, and the American Medical Association strongly endorsed the bill. Unfortunately, it could not compete successfully with other legislation. We can only

hope that the American people will demand passage of such a bill if one is introduced again, as surely it must be.

There is, indeed, no lack of moral support for full development of local health services. The organizations I have mentioned have been joined by other strong civic groups, such as the Farm Federation and the General Federation of Women's Clubs. More recently, some of the voluntary health agencies have begun to see the importance of the local health unit to their own programs.

Federal legislation, however, is not the only requirement for nation-wide local health services. State and local governments must take more responsibility. They must support the recommendations of their central health agencies for well planned, state-wide development of local units. State and local action, in fact, must be the spark plug for increased federal support.

All organizations must work with the public at state and local levels to get the comprehensive health services the people need. The federal government can only bear its share of the responsibility for leadership and help. The needs arise in the communities and the states. So must action arise in the communities and the states.

I suspect that the health officials, the professional and civic leaders, need to recapture some of the missionary spirit which 40 years ago inspired the pioneers. We, in the Public Health Service, have inherited that spirit from such rugged pioneers as Lumsden, Frost, Carter, and others. Many of us were trained by those men. We are still somewhat baffled to find that it is harder to "sell" legislative bodies on the idea of the local health unit than on attacking a particular disease. Some say that the local health unit lacks drama. No man who walked down the country roads with Lumsden 30 years ago would agree.

When Lumsden began his rural health campaign in 1914, our self-confessed "*Shoe-leather Epidemiologist*" sent his boys from house to house preaching the gospel of the sanitary privy. But his aim was what is now the Number 1 goal of public health: the modern, model, all-purpose local health unit. A unit adequately staffed with well trained physicians, public health nurses, health educators, sanitarians, technicians, and other needed specialists. A unit housed in a functional, good-looking building—the health center. A service, conveniently available to all citizens; working jointly (even under the same roof) with the local hospital and private physicians.

Lumsden's methods were as direct as his plan was far-reaching. You went into a county where the death rates were high and the flies thick. You went from house to house and explained to the families that typhoid, hookworm, and the "summer complaint" which killed their babies, came from their dilapidated backhouses. You showed them how and why a nice, fly-proof, sanitary privy would help protect their health. You persuaded them to rebuild. (Later, you went back—or Lumsden would want to know why you had not—to see whether they had done anything about it.) You gave lectures on sanitation—in churches and one-room school houses. You rounded up prominent citizens, and gave them an extra earful.

By the time you had finished this softening-up process, they were glad to invite you to survey their community and tell them what to do. Probably you already knew what should be done. But you made that survey with the same attention to detail, the same curiosity (for you might run across something unusual anytime), the same zest that filled you the day you decided to go into the Public Health Service.

The purpose? "The ultimate purpose," Lumsden wrote in 1916, "is to awaken in rural communities an indi-

vidual and communal interest in public health questions, which in turn will lead to an improvement in sanitary conditions and *the maintenance of an official local health agency.*" To this day, Lumsden's boys fondly recall that this purpose is what puts "the foolish glimmer in your eyes."

The Public Health Service could give little help for attaining that vision until 1936. For a few years after World War I, the Public Health Service had as much as *half a million dollars* to help interested states in developing local health work. But by 1928, the recession of public health work was on its way to the bottom. The Service that year had only $350,000 to spread among 204 counties in 17 states.

In that year, one of my distinguished predecessors, Dr. Hugh S. Cumming, revealed in a single sentence, the discouragement of health agencies throughout the country. "At the present rate of progress," the Surgeon General wrote, "about *fifty-one* years will be required before all the rural communities in the United States will be receiving adequate health service, the lack of which is responsible for an annual economic loss of one billion dollars."

Twenty of those 51 years are gone. This year, the Public Health Service dedicates itself to cutting that predicted time lag by at least 25 years. We must attain complete coverage of the country in the next 5 years. It would be ironical indeed if the richest nation in the world should take longer than a generation to complete a task so well begun, and so vital to the well-being of its people.

COMPREHENSIVE, MAXIMUM SERVICES

The public health agencies and professions need to take a broader view of the services required in our communities. What would have been the outcome if, say 10 or 20 years ago, the official health agencies and professional societies had broadened their concept of a local health unit's functions? That question perhaps can never be answered. But it may not be far from an accurate surmise that the current imbalance in many public health programs is a direct result of the "minimum service" point of view.

The need for the so-called "basic services" cannot be denied. But they are not enough, and they have never been enough. As nature abhors a vacuum, the voluntary agencies rose naturally. They rose from the American people and the American drive to get things done, to fill vacuums left by traditional and inadequate public health programs.

May there always be voluntary agencies to spearhead needed action! May there never come a time when only official agencies are active for the people's health! No thoughtful health officer can overlook the significance of these popular movements, devoted to the cause of particular population groups or to the conquest of a particular disease. In each instance, the public health programs had failed to give that problem the attention it deserved. Voluntary effort must always be welcomed and fostered in our country.

In this Atomic Age, full preservation of our man power is vital to the very existence of democracy in the world. Neither state, local, or federal governments, nor voluntary agencies, nor professional organizations, nor the people themselves, can afford to shirk their full responsibility to work together for higher levels of health.

I spoke earlier of the present interest of the Public Health Service in simplifying the administration of grants-in-aid to the states. It must be clearly understood that our ability to do so will depend on evidence in the state plans that the states accept their responsibility to carry forward the attack on inadequate health services of all types.

We expect the special programs, stimulated by federal support, to be pressed with greater vigor.

Moreover, there are many fields, clearly within the province of public health work, in which the states should pioneer without the stimulus of "categorical" appropriations by Congress. Housing, for example, holds first rank in social problems of today. Despite the distinguished studies made by the American Public Health Association under Dr. Winslow's direction, healthful housing has had almost no attention by official health agencies.

The relation of housing to the spread of communicable diseases is too well known to merit discussion here. The amazing point is that the problem is so well known, and that so little is done about it. The effects of poor housing on mental health can only be surmised; but we cannot ignore, as indices, the rising rates of juvenile delinquency, divorce, and violent death in familial situations. Home accidents, too, rank high as a cause of death and disability. Public health agencies, it seems to me, can no longer ignore the problem of housing.

The Public Health Service began a few weeks ago to assume its responsibility in this field. Our engineers are working with the various federal agencies concerned with housing to define the areas of health interest in the total problem. We expect them to come up with recommendations for public health action. The state health agencies also should give more attention to the housing problem in their jurisdiction. The United States can no longer afford to tolerate, for example, the woeful conditions in many of the "fringe areas" beyond the corporate limits of our populous cities, often beyond the protection of municipal sanitary and construction codes.

I mention housing as an example of problems which exist or may arise, and which should be given attention in current public health programs. There are, of course, many other important services, partially developed or neglected. My purpose is to stretch the minds of public health workers to a realization that theirs is a dynamic job; that they never can be satisfied with what *has* been done, or even with what *is* being done. Our satisfaction can be only in keeping a perpetual vigil over the needs of the people we serve, alert to new problems and new methods.

The local health unit is an ideal instrument only so long as it is flexible; ready to take the leadership in introducing new programs; ready to follow the lead of the community it serves, demonstrating the peculiar genius of the American people to accomplish their social aims by the coöperation of governmental and voluntary agencies.

TRAINING OF PUBLIC HEALTH PERSONNEL

The ideal local health unit will remain a dream so long as the men and women who serve in it lack the training they need. Estimates made by the National Health Assembly last May show that training is needed for at least 60,000 persons in order to provide minimum staffs for nation-wide health units.

The concept of formal training for public health work took shape only 30 years ago, when the first graduate school of public health was established. Others followed rapidly, but even today there are only 9 accredited schools of public health in the United States. A new one, as most of you know, is being developed in the University of Pittsburgh by former Surgeon General Thomas Parran.

During the past 3 years, the Public Health Service has developed a comprehensive program for inservice training of its own professional personnel in research, clinical, and public health

branches. Likewise, we have been able to help the professional schools to expand their research and training programs in the special fields of cancer and psychiatry. Under the new programs for dental research and heart research, we shall be able to give similar assistance in these special fields. As yet, however, we have been unable to give general assistance to the professional schools.

The Public Health Service proposes to expand its training program for its own employees to the limits of its legal authority. Our task would be made easier if the young doctors, dentists, and nurses who come to us from their basic training had been better indoctrinated in the principles and practice of preventive medicine during their undergraduate days.

As the field of public health widens, the variety of special knowledge and skills increases. On-the-job training and inservice training are needed in every area, in order to keep staffs up-to-date. Too few state health agencies have developed the type of training program which will improve their chances for recruiting competent workers and increase the efficiency of existent staffs. The state health departments which have developed comprehensive training programs are benefiting to an extent far in excess of the expense and effort involved.

The total problem of professional education requires both study and action. A series of Acts of Congress, beginning in 1945, has given the Public Health Service an increasingly heavy responsibility and broad authority to augment medical research generally, and training in special fields. Our advisory councils, who must study and recommend the approval of grants to outside institutions, have felt the need of objective data as a basis for their policies and actions in this field.

About two weeks ago, the National Advisory Health Council recommended that the Public Health Service undertake a thorough study of its research and educational grants and fellowships programs, including the costs of medical education. "One of the chief purposes of this study," the Council reported, "is to determine whether present Public Health Service programs or other methods may be recommended for the improvement and extension of medical education."

By assembling data on the costs of teaching facilities in relation to the total costs of medical education, the Council hopes to be able to evaluate the effect of the grants programs on medical school finance and on medical education. The Council further recommended that a special committee be appointed to develop the study. We are hopeful that the study will provide a basis for similar analysis of other branches of professional education in which the Public Health Service has a specific interest.

The broad functions of the Public Health Service, obviously, give us an interest both in basic training of the major professional groups, and also in their graduate work. At times in the past, I believe that our colleagues, and even some of our own officers, have forgotten that when, in 1912, the 62nd Congress gave us our definitive title, the Public Health Service, it did not exclude—but specifically included—our medical care programs. There has never been a time in our 150 years of existence when the Service was not the major federal agency for civilian health. This was true when the Service was a handful of locally operated hospitals for sick and disabled seamen, as it is true today. The difference in functions is one of perspective, not of haphazard addition of responsibilities.

Our first hospitals are among the oldest general hospitals in the United States. The Boston Marine Hospital, for example, is the fourth oldest in the

country, preceded only by the Pennsylvania Hospital in Philadelphia, the New York Hospital (now Bellevue), and Charity Hospital in New Orleans.

Very early in its existence, the Marine Hospital Service had a close relationship with medical faculties and the training of physicians. As early as 1804, the Boston Marine Hospital became the first teaching hospital of Harvard Medical College, through the efforts of one of the giants of American medicine—Benjamin Waterhouse. Dr. Waterhouse was on the original faculty of the medical school, and served as physician-in-charge of the Marine Hospital for 4 years. He was among the first medical educators to realize the inadequacy of the didactic instruction and apprenticeship of those days. The Boston Marine Hospital was the scene of his experiments in applying new European methods of hospital administration and professional training. Waterhouse is also remembered as the physician who introduced vaccination in the United States.

I have dwelt upon some of these early activities because we sometimes overlook the close relation of the beginnings of preventive medicine and hospital care to public health. It is common to set the origin of the public health movement in the great sanitary reforms of the latter half of the 19th century. The importance of sanitation, and its place in the foundation of the public health structure, cannot be—and is not—disputed. In the light of modern knowledge and modern concepts, however, we are coming to see that "public health" is not and never has been a thing-in-itself, but a part of a larger whole: man's social effort for the conquest of disease and the attainment of health.

Such a concept includes the achievements of clinical medicine, the professional schools, the private hospitals, as well as the achievements of public agencies in the field of medical care. It includes the whole history of medical research in this country, a field in which state health agencies should be much more active. And, of course, the total concept of public health includes all those collective efforts by official and nonofficial agencies to apply preventive measures for the protection of all the people.

By some insight, conscious or dimly sensed, the people of the United States through their Congresses have maintained in the Public Health Service that unity of functions—research, clinical medicine, and public health administration—which constitutes the public health movement of today. There may have been times in our history when the Service has not been conspicuous for the excellence of its performance in all of these fields; but I think it is right to say, those times have been few.

Since 1939, the Public Health Service has been a constituent unit of the Federal Security Agency. That shift placed the Service where it could best grow and develop to fulfil its destiny; that is, it placed the major health agency in close administrative relation with the educational and public welfare programs of the government. The health policy of the United States Government, as represented by Congressional Acts and the work of the Public Health Service, the Children's Bureau, and related programs, has never been partisan, nor even bipartisan. It is non-partisan. We of the Public Health Service and our federal colleagues are going to do all in our power to keep it that way.

The Public Health Service is a public servant. Each member of our team is proud to name our calling. We take this role to mean that we do the chores assigned to us by the people of the United States. But it is no "hired man's" job. To us, it is a task calling for an incredible variety of skills, abilities, and knowledge; a task calling for

creative thinking of a high order. It calls also for leadership, rather than routine obedience. Unless we can bring these qualifications to the job of public servant, we cannot discharge its responsibility with the moral and intellectual integrity it demands. The job also offers limitless possibilities for satisfying work with colleagues in scores of professions, hundreds of institutions and health agencies. Collaboration in man's great quest for health is, to our way of thinking, the highest human indeavor.

We expect to go on serving in that capacity with the same good, self-imposed discipline and integrity which our professions and our predecessors in the Service have taught us. The Public Health Service has one sole interest: *to do* and *to be* only what is best for the health of the people. As in the past, we await their orders.

Canada Acknowledges A.P.H.A. Resolution on National Health Program

The following letter has been received from Paul Martin, Minister of National Health and Welfare of Canada in reference to Resolution 21 adopted by the Association and published in January *Journal.*

"I wish to express to you and to the members of the Governing Council of the American Public Health Association my thanks for the very encouraging resolution relating to our new National Health Programme which was adopted at the recent annual meeting in Boston.

"We are convinced, of course, that the programme is of great significance and promises possibilities for tremendous developments in the health field of this country. I believe we have an opportunity to do really helpful things for our people. Naturally that is my first concern. However in addition and possibly in the long run just as fruitful, there is a wonderful opportunity for new thinking, new projects, and significant developments in health work. Such possibilities naturally are most intriguing and challenging.

"It is in this latter connection that I wish to tell you how much we in this country value the very fine relationships which our health officers enjoy with those of the United States. This is true not only of individual workers, but, also of great voluntary organizations such as your Association and of government officials at all levels. The hospitable way in which we are always received in the United States and the generosity with which advice and information are always tendered is a matter of great pride and satisfaction to us. I know quite well that this spirit of coöperation and this helpful collaboration will contribute much to the maximum development of our new programme.

"Again may I express our gratitude for the resolution. I hope you will find it possible to convey this message to the members of the Council."

Anniversary Program—150th Year, U. S. Public Health Service

Training of Health Man Power *

LOWELL J. REED, PH.D., F.A.P.H.A.
Vice-President, Johns Hopkins University, Baltimore, Md.

IT is a privilege to speak at this meeting which is devoted to commemorating the one hundred and fiftieth anniversary of the U. S. Public Health Service. All of us who have been working actively with the Service during the period of its greatest growth and are now sharing in its efforts to make public health mean the health of the public, take great pleasure in its past developments and in the prospects ahead. This rapid growth has brought to the fore the fact that our present programs and those that we envision for the future cannot be successful unless we make more adequate provisions for developing the necessary personnel. It is therefore appropriate that someone should discuss the topic assigned to me today.

As in the case of all large-scale social movements, our problem is that of providing the staff of workers needed for the task, and this involves not merely the setting up of the mechanisms for appropriate training but also the more difficult one of recruiting the individuals to be trained. I shall, therefore, discuss both phases of this question and suggest certain possible solutions.

As an approach to the subject, we might review briefly past approaches to the problems of recruitment and training and the present status of such efforts.

During the early stages of the public health movement, programs were left to some public-spirited individual, usually a doctor who, on the basis of such training as he had had, served as health officer. The subordinate personnel, if there were any, had no specific training. Among the early approaches to education directed expressly at public health, stands the London School of Tropical Medicine, by means of which England undertook the training of medical officers for the colonies. Although these men were called medical officers, their activities were primarily in public health, and in this effort we see a deliberate attempt at health officer training. A more unique approach to the matter was the early school at the Massachusetts Institute of Technology where, under the stimulus of Sedgwick and Whipple, the disciplines of biology and engineering were united in an approach to health matters. The emphasis here was on the sanitary aspects of public health work, that being the most important problem of that time. A number of the people now active in public health work are products of that school and of that stimulus.

As the scope of public health increased, the need for giving more specific public health training to physicians became apparent. The result was the setting up of training centers in public health, either as independent schools or as departments within medical schools. In either case, efforts were mainly devoted to the developing of appropriate

---

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

Paper No. 248 from the Department of Biostatistics, School of Hygiene and Public Health, The Johns Hopkins University, Baltimore, Md.

training for health officers under the concept that had been growing within this country that health officers should be graduates of medicine. These schools, however, did not limit themselves to the training of health officers but immediately started to develop training opportunities for the variety of specialists other than doctors of medicine. As a result, we now have graduate training opportunities for such classes of public health specialists as bacteriologists, parasitologists, epidemiologists, statisticians, sanitary engineers, industrial hygienists, nutritionists, public health educators, specialists in the public health aspects of tuberculosis, venereal diseases, maternal and infancy hygiene, and in many other fields.

The teaching centers offering these varieties of training have been organized into a system of approved schools of public health, which provides for a certain unification of the educational efforts without impeding the development of new courses of study. The addition of new schools, such as the one recently announced at the University of Pittsburgh, and the initiation of new interests in the schools already established, assures us, I believe, that we shall have reasonable coverage in so far as graduate and postgraduate training is concerned.

In this educational movement, however, there is an inherent weakness, in that we have set up a graduate pattern without making the necessary provision for the flow of personnel from the lower programs of education into this graduate field. Looking back, it is easy to see that the mistake was a natural one, for so much of the thought thirty years ago was concerned with the question of training medical men to be health officers that the educational flow was assumed to be that of a premedical course, training in medicine, and then graduate work in public health. The problem of new recruitment was supposed to be that of stimulating medical men to take this training and to encourage this result; courses in preventive medicine were introduced in the medical schools. This approach to the problem overlooked the need for revealing to young men and women interested in fields other than medicine the opportunities that existed for them in the area of public health. Movements in this direction were made through the establishment of courses in public health at the college level. Unfortunately, however, in the period of intense interest in developing graduate schools, there was a tendency—conscious or unconscious—to frown on these efforts at the undergraduate level, and progress along these lines has not been what it should have been during the past generation.

In a talk given to a similar audience a year ago, I called attention to the fact that the shortage of personnel apparent in so many of the activities of society is not, as a great many people assume, a product of the war, but is rather a result of the fact that the man power demands of our highly industrialized society and of our expanding social programs exceed the supply in our present population. Competition for the brains and abilities of young people will be more intense in the generation to come than it has ever been. There is no way for the field of public health to face this competition except through the development of an interest in public health on the part of our young people at college and at high school levels.

Looking at medical education, we see that here we were forced to establish, on a systematic basis, premedical courses for the man going into medicine. Without the establishment of such courses we would not have had, and would not now have, the flow of well qualified young people into the field of medicine that is needed to keep up our supply of physicians. It is my opinion that the creation along similar lines of a "pre-

publichealth" course offers one of the most important approaches to our problem of recruitment and training. It would be desirable for the agencies that do the broad planning for public health, that is, the American Public Health Association, the U. S. Public Health Service, the Association of State and Territorial Health Officers, and the schools of public health, to consider seriously an organized approach to undergraduate training in public health.

It is well known to all of you that certain universities do offer such training, but the movement has none of the stability and force that has been achieved in the graduate program. We almost seem to be building an army of generals in public health without the necessary soldiers.

I cannot leave this subject without presenting some of my concepts with regard to this undergraduate course. I believe that it should be, in so far as possible, a unified course for the wide variety of people going into the field of public health, and should not be framed in such a way as to encourage too early specialization. There are certain basic disciplines at the collegiate level that all persons should cover if they expect to carve out a real career along the lines of any one of the numerous activities embraced under the title "public health."

In general, the four years of collegiate training should include specific courses in the natural sciences including mathematics, in the social sciences, in psychology, and in those general cultural subjects that all college students are encouraged to include in their curriculum.

The case for the natural sciences is clear. The public health movement is so firmly based on scientific findings that no young person should be encouraged to enter the field of public health without a fairly substantial training in the sciences at the collegiate level.

Neither is there any argument with regard to the social sciences; public health being a social activity, students should take specific courses in this field. I should include within this group, not merely the usual courses that one thinks of under the heading of social science, but I should like to see developed a course in what might be called "social economics"; also a course in geography which would embrace training with regard to human populations and the relationship of these populations to their environments and their natural resources, since knowledge of these factors is basic to public health work.

A course in psychology is desirable because so much of the work in public health has to do with the question of human relations, and a general course in this field can furnish an excellent basis for an understanding of some of these forces.

The remainder of the 4 year course would be, as previously stated, filled in with general cultural subjects.

If properly developed, graduates from such a course would not be debarred from entering the field of medicine, even though they had not taken a premedical course. This would be a desirable thing because our present training program in medicine demands a rather early decision on the part of our young people as to whether or not they wish to enter medicine. We thereby tend to lose certain excellent individuals from medicine that we might have available if their training in the type of course described were such as to enable them to make the decision to go into medicine at some time toward the end of their collegiate career.

Graduates of such a "pre-publichealth" course would be suitable material for the numerous public health positions at the technical level below that of heads of departments and divisions. But more important than that, this course would provide a steady flow of young

people stimulated to thinking about public health and to developing careers in this field, and from this group we might expect to get the wider variety and the increasing number of graduate students that the future of public health demands.

Another opportunity for training in the field of public health which offers a good deal of promise, is that of inservice training. Various approaches to this problem have been made and in the past a great deal of pressure has been put on the schools of public health to develop such training as an active part of their own program. I should like to say that I believe this to be a mistake. Sound inservice training programs can best be provided by the operating agencies in public health. The schools should be expected to supply lecturers for such programs, and to coöperate with the plan in other ways, but I believe that it should not be left to the schools to take the initiative here. I should like to see all of the larger health departments add a person to their staffs whose function would be that of education. Their return for the support of such an individual would be the improvement of their personnel within all lines of departmental activities. Certain health departments have done this to some degree, and in every case that I know of, it has borne fruit.

One final area for training in the field of public health that should not be overlooked is that of education of the public itself. In the days when the public health movement was small, this was relatively unimportant, but now that we are engaged in a full-fledged social program, it becomes increasingly important that the public be constantly educated as to the meaning and the objectives of public health. In this, the public health educator is an important person. His functions, however, are not very clearly defined because the field of public health has no real program for education of the public. It would be wise therefore to leave the training of public health educators in a fluid state until more experiments in this type of education have been conducted.

With regard to our approach to the problem of training the public, it would be well to note the movement in relationship to the public school system that has resulted in the organization of Parent-Teachers Associations. We need similar public organizations in the field of public health. No one has yet proposed a plan under which these might be developed, and in many cases the health officer has had a tendency to discourage active interest in his problem on the part of community groups. The fact that the public will take an active interest in health problems is clearly indicated by a variety of minor specific instances; one that has attracted my attention recently was the eagerness with which people in different blocks in the City of Baltimore were willing to form teams in a program for cleaning up the rats of the city.

The fact that general interest in public health can be awakened around specific needs, such as poliomyelitis, heart disease, tuberculosis, cancer, etc., has led to the growth of powerful public organizations in these fields. These groups benefit from the fact that they are devoted to specific problems, but this fact is also a weakness in our development of a balanced health program. Perhaps the one general field that the population of this country has shown an interest in getting behind is that of "medical care." If we can maintain this concept on a broad basis, it might be made the keynote for an approach to the education of the public in health matters. At any rate, there is an opportunity for leadership in public health to furnish the people of the country with additional outlets for their energies and interests in health problems. When we have such an outlet on a comprehensive rather than a specific

basis, our program of education of the population in general with regard to public health will be a simple one and the field of action of the health educator will be clarified.

I have painted a rather sweeping picture of training in public health. I have done this deliberately because I feel that at a meeting such as this, where we are celebrating the anniversary of the organization that is set up to supply leadership, it would be well to take a broad point of view. I feel confident that the future will see developed many of the areas that I have discussed here and indeed many others that I have failed to mention, and in all these new movements the stimulus and leadership of the U. S. Public Health Service will play an important part.

Problems of Training of Professional Public Health Workers

A meeting, called by the Federal Security Administrator, which dealt with the necessity of training large numbers of professional public health workers, was held in Washington, D. C., on January 8, 1949. Participants at the meeting were members of the staff of the Federal Security Agency (inclusive of officers of the U. S. Public Health Service), deans and faculty members of schools of public health, and the Chairman of the Executive Board of the American Public Health Association

Questions discussed were:

1. How much would the average annual training load have to be increased if future public health needs are to be met, and what proportion of the total average training load should be carried in the graduate programs of accredited schools of public health?

2. How would an increase in enrollment in the schools of public health affect the financial plight of the schools and what consequences might result if financial assistance were not extended to schools of public health?

3. What formula for federal aid to schools of public health should be devised (a. black grant: b. capitation; c. construction)?

4. Since most public health workers prepare themselves for governmental positions not offering liberal remuneration, can recruitment for training be expected to be successful unless financial assistance is offered to the students?

5. What formula for direct aid to the students appears most appropriate (loans, scholarships, tuition, travel, stipend, grant)?

6. With changing horizons in public health, how should the present curricula of the schools be modified?

It was agreed that during the next 10 years, an annual average of nearly 7,600 professional public health workers in the following categories must be trained: physicians, nurses, engineers and other sanitation personnel, dentists, health educators, laboratory workers, hospital and medical care administrators, nutritionists, and statisticians. It was further agreed that 29 per cent of the total number of 7,591 should be trained in the graduate programs of schools of public health (accredited by the American Public Health Association). The participants also approved formulae for aid to the schools and for the amount of fellowships to the various professional groups of public health trainees.

Anniversary Program—150th Year, U. S. Public Health Service

A National Health Program—What the Public Expects, and How to Organize It *

AGNES MEYER
Washington Post, Washington, D. C.

NONE of our federal agencies deserves the commendation and gratitude of the American people more than the U. S. Public Health Service. My respect for its contribution to the nation's stability was acquired during the war. As I studied the social chaos that prevailed in all of our major production centers, the field men of the U. S. Public Health Service, under the wise leadership of Dr. Parran, seemed to be the only people who knew exactly what they were to do and how to do it. What I admired most about their outstanding achievements was the effectiveness with which this federal agency worked with state and local governments, with voluntary organizations, and with the numerous Army and Navy officials. The decentralized administrative policies of the U. S. Public Health Service are, in fact, the best example we possess that federal leadership of state and local endeavor can be achieved without federal domination.

In planning for a national health program, nothing is more important than the preservation of this thoroughly American tradition of federal, state, and community coöperation, if our country is to remain a republic. The battle over the organization of a nation-wide health program has been so violent because its solution will go to the roots of our existence as a nation of free men. What we must try to achieve is health not only of the individual but of society itself. Democratic ends demand democratic means for their realization. Our people must face the fact that if they want truly civilized, humane, and serviceable institutions, if they want health in its widest aspects, mental, physical, moral, and even political, then they must achieve it in their own good way. Assuredly they will have lost their most cherished characteristics—their individualism, independence, and freedom—if they meekly allow the experts to set the patterns for their thinking. They must make their own institutions, or their institutions will make them. Therefore, this problem of nation-wide health programs is a question on which every responsible citizen must take a stand, for the answer to it will affect the whole destiny of our nation.

Yet the medical groups who seem to think they are defending individualism and freedom when they blindly oppose every coöperative endeavor of the lay public, must realize that we have a mass health problem on our hands and the mass of the people want action. And action there will be, whether right or wrong. The election results are clear proof of this. As a Republican who testified fruitlessly before the 80th Congress on behalf of various welfare measures,

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

I am convinced that the overwhelming Republican defeat was due mostly to the obstruction of social progress by the House leadership. I hope the American Medical Association will take the lesson to heart. At present the people still look to the medical profession and to you public health workers for guidance and leadership out of their confusion, but whether they get it or not, they will not be denied the elementary rights to which they feel every American citizen is entitled.

It is essential that the public should be informed on the actual progress toward sound public health planning that already exists in many of our states, and on a nation-wide scale. Many people who advocate a revolutionary, over-centralized, federally dominated organization for health protection, do so only because they see no other alternatives. Therefore, the best service I can render here is to outline our most constructive experiments toward a national health program as well as it can be done in a few minutes.

Since health is a function of the community's total way of life, the furtherance of health is dependent in our democratic nation upon local initiative, support and participation of the entire community. It is also dependent upon such closely related factors as education, housing, nutrition, and a basic standard of living. Therefore the first step toward dynamic planning for health is the formation of state and local citizens' councils wherever they do not already exist, to serve as the conscience of the community on all matters of the general welfare.

These councils should bring together lay and professional groups and individuals for the study and solution of their health problems, and for the correlation of all services affecting health. These councils should be appointed by the governor or mayor if their reports are to carry weight with officialdom and with the people. They should join forces with local health departments and with the state hospital authorities appointed by the governors under Public Law 725. This would be the quickest way to achieve coöperation between public and private endeavor and the surest method of eliminating the hostility between the expert and the civic leader that is now one of our chief handicaps toward social progress. These councils should gather factual data to establish existing health needs, and develop methods for the effective implementation of planning.

Only by the encouragement of this grass-roots movement, only through intimate face to face associations and the satisfaction to be derived from a sense of sharing in creative activity, can we control the frightful impersonality of centrifugal forces and get the necessary impetus behind a sound national health program. At the same time our people would realize the difficulties involved in the organization, administration, and financing of a national health program that will be effective, while remaining responsive to changing community needs and to the scientific progress of medical care. The utopian promises of compulsory national health insurance have lead some of our people to think that all we need is federal legislation to implement it and, presto, every medical need will be met. Advocates of the Murray-Wagner-Dingell Bill should never lose sight of the hard truth that a national compulsory insurance program supplies merely organization and money, but does not supply hospitals, doctors, nurses, dentists, and other essential personnel. If our citizens learn by direct participation in planning for their own health that the problem is closely enmeshed with their daily lives and with the availability of local facilities, they will be sure to reject authoritarian over-centralized plans that might destroy the very aims they seek.

Since local health departments meeting minimum standards are now available to no more than one-third of the country, these citizens' councils should demand that this basic service be made available to all the people without delay. Dr. Haven Emerson asserts that "not more than 4 or 5 per cent of our people are today receiving a local public health service that measures up to the simplest demands of science and to an art of preventive medicine which our state of general culture has a right to expect." He estimates that about 1,200 such local health departments staffed with qualified persons would suffice to cover our entire continental population instead of some 18,000 now operating under frequently inferior conditions of personnel, and serving but 67 per cent of the population. We must insist upon the total coverage of our people by local health units capable of putting the science of preventive medicine to work for the whole social structure. There is not a single goal, whether in the field of public health service, of medical care, of nutrition, of education in health, that can function until we achieve these health departments in each community.

Dr. Emerson estimates that between 55,000 and 60,000 employees will be required to staff these 1,200 local health departments in order to give the minimum health service to all the people.

That means the immediate recruiting and training of skilled people in adequate numbers. It will also take legislation on local, state, and federal levels to finance the program. A bill to help the states finance these local health units on a matching basis was introduced in the last Congress. Most of our states can and should finance their own health departments. Yet federal aid will certainly be needed in some twelve of our less productive states.

What we need to determine the financial responsibility in this and all other welfare programs, is a clarification of the administrative and tax relationship between the federal, state, and local governments. If we do not hasten to clarify these relationships, we shall find it very difficult if not impossible to do so in the future. For we shall find ourselves too deeply committed to over-centralization and a top-heavy bureaucracy, simply because the taxing power is too heavily weighted in favor of the federal government.

To improve the coördination of health facilities in state and local governments, all major federal health agencies should be grouped together under the U. S. Public Health Service. Federal, state, and local health agencies must also work more closely with the public schools, and our educational system everywhere should be improved and equalized as between geographical areas. Health without education and education without health are both impossible.

In order to have fewer sick people and fewer people with sicknesses, development of a preventive health program, based upon constant research, should go hand in hand, if not with precedence over the expansion of curative facilities. In deciding this question of priority, our whole philosophy of democratic living is involved. Have we positive aims for the reinvigoration of the human mind, body, and spirit, or are we merely interested in alleviation of the suffering created to a great extent by our social defects? Far too much of our welfare work is now devoted to compensating people for misfortune that might have been prevented. To be sure, we must protect the sick, the weak, and the incompetent. But it is high time we spend more of our energies on protecting the well, the strong, and the talented, if our nation is ever going to develop its fullest human, civic, and ethico-political capacities. If we are not to build a gigantic centralized welfare-state in which the politicians take over the rôle of guardians, our liberty must be the means of creating

and promoting the superior individual.

After all, the Department of Agriculture spends billions for the promotion of the health of cattle and the productivity of the soil. It would pay infinitely greater dividends in cold cash, to say nothing of higher values, to promote the total well-being and the productivity of our human resources. Just as the county agent of the Department of Agriculture puts the latest expert knowledge about agriculture at the disposal of the farmer, so the local health officer must put the fruits of research on preventive medical care at the disposal of the people as a whole. This preventive program must also become the link between the individual and the curative organizations.

How then do we develop our hospital system so that its services are accessible to all the people, and how do we finance such services?

To salvage the unique system of hospital services and connected medical training that we now have, is a first essential step. The enormous cost of free hospital care for relief patients was formerly met in these voluntary institutions by payments of the middle and upper income groups and by voluntary gifts. Now these sources of income are drying up while the various costs are skyrocketing. In most big cities, the municipal governments already pay for part of the free care of the indigent. It seems obvious that every municipality should now pay the total cost for the treatment of its relief cases, whether in the hospital or for outpatient services. In some cities the state will have to supplement the city payments in proportion to the local tax resources. If the hospitals were relieved of the heavy costs of free care, they could use their endowment funds and other financial resources to reduce charges very considerably for the lower and middle income groups.

To make sure that charges to the middle income groups will be lowered as the states and municipalities take over the total cost of free care, the cost-statements of voluntary hospitals, that furnish the basis on which the state pays the hospital for its services, should be subject to review by the state auditor. This practice already exists in several states. In Maryland, for example, the state, counties and cities have already accepted the responsibility for the relief load, though they do not as yet carry it in full. The machinery is a contractual relationship between the hospitals and the board of health. By this gradual, evolutionary approach toward the redistribution of hospital costs, Dr. Lowell J. Reed, Vice-President of Johns Hopkins University, is convinced that better care can be secured for the average person at a price he can pay than by a nation-wide revolutionary upheaval in the financing and distribution of medical services.

Since the hospital is the basis of medical care, the federal government cannot at present underpin a national health program more soundly than by expanding the hospital facilities of the country through the Hospital Survey and Construction Act. If the plan for the decentralization of hospital care is carried out, we would then have the large central hospital with its medical school, making available its specialized facilities to the subsidiary area hospital, to the smaller community hospital, and to the local health center. All the benefits that modern medicine has to offer would be chanelled from the large modern medical centers to the remotest rural hamlet. From the top down would flow an educational program, both inservice and preservice, for all types of health personnel—physicians, dentists, nurses, technicians, and others. On the other hand, there would be a referral of patients from the small community health center, to the area or community hospital, and to the large medical center.

The introduction of planning for hospital and other health service on a regional basis demands the immediate integration of the Army and Navy hospitals and the Veterans' hospitals with those to be constructed under the Hospital Survey and Construction Act.

At present the government is not doing as well as it should by the long-stay patients, the mentally and chronically ill, and the tuberculous cases. The Commission on Hospital Care has pointed out that the care of mental illness and chronic diseases should be decentralized and integrated into the general health program of each community hospital, with special emphasis on prevention. "When that happens" said Graham L. Davis, "those diseases will disappear as major health problems."

In order that the Hospital Survey and Construction Act may serve the needs of the entire nation, its appropriations should be increased and its provisions for financing of construction and administration amended. The areas with inadequate tax resources cannot possibly carry two-thirds of the load and therefore cannot benefit from the Act in its present form.

If we take for granted that the best medical care shall be available to all of our people, how is it to be financed for low income groups?

I have time to consider the thorny problem of compulsory versus voluntary insurance only in its broadest aspects. The construction of adequate hospital facilities and the training of sufficient personnel to staff them must have first call on public funds, for no system of insurance, voluntary or compulsory, can have validity without them. If we rush into compulsory national insurance, the drain on public funds would be so great that the coverage of the nation with properly staffed health departments and the nation-wide implementation of the Hospital Survey and Construction Act would be impeded, if not impossible.

On the other hand, it is also a fact that we shall be forced to accept compulsory national health insurance before very long, unless we make a greater success of voluntary health insurance without delay, especially for the low income groups. The fear of sickness and the high cost of modern medical care must be lifted from the minds of our people. To achieve this end, the medical profession must throw itself wholeheartedly behind all coöperative insurance plans whether for medical service or hospitalization. The local medical societies must encourage, instead of blocking, the efforts of the Blue Shield to establish standards and to develop complete coverage of medical service. The various independent insurance systems in industry, labor unions, and other groups have come into being only because the Blue Shield has not improved the range and quality of its medical care. The first requisite is a predominance of laymen on the local boards. It is significant that the Blue Shield, which is dominated by doctors, has no standards of medical care, whereas the best coöperative insurance groups under lay control have succeeded in establishing standards over the opposition of the medical profession.

As a matter of fact, the pretensions of the American Medical Association that the doctors must control the development of a national health program if it is not to create what Dr. Fishbein calls "peasant medicine," cannot be substantiated by experience. The voluntary hospitals, America's pride, which are managed by lay boards, have always insisted upon standards, whereas the proprietary hospitals, whose boards lack consumer representation are mushrooming all over the country, because they have no standards and any doctor with a license can work in them regardless of his qualifications. With the whole-

hearted coöperation of the American Medical Association, the Blue Cross and especially the weaker Blue Shield could raise the standard of medical care all over the country. The innumerable voluntary insurance plans if pulled together under the Blue Cross and the Blue Shield would then create the two strong nation-wide insurance organizations we need. Moreover, insurance groups as vast as this could modify their rates for various parts of the country and reduce the rates for the membership as a whole. The names of these organizations do not matter. The important thing is that we achieve a unified system.

Health education and national health programs must be built from the community upward. But the process need not be slow if the state and federal public health officials as well as the medical profession do their share and mesh their efforts with those of the hometown folks. With determination, applied intelligence and coöperative effort on every government level, and between civic and professional leaders, we can transform the health picture in this country within five years and make it possible for every American family to obtain the medical service it needs, and for every American child to develop its maximum potentialities. We must all work together loyally and prove that democratic methods can deal effectively and quickly with all of the dynamic problems of the day.

Harvard Develops Training Program for Cancer Control Officers

According to the *Harvard Public Health Alumni Bulletin,* the Harvard School of Public Health, Boston, has received a substantial grant from the U. S. Public Health Service and the Massachusetts Division of the American Cancer Society to organize a program for the training of cancer control officers to fit them for the administration of cancer control work in either official or voluntary health agencies and for epidemiologists, statisticians, and health educators in order to prepare them for effective participation in cancer control programs.

Leonid S. Snegireff, M.D., Dr.P.H., who has been appointed Associate Professor of Cancer Control in the Department of Public Health Practice, will have charge of the program, which will be closely integrated with the new Cancer Detection Clinic at the Palmer Memorial of the New England Deaconess Hospital and with the cancer control programs of the Massachusetts Department of Public Health and the Massachusetts Division of the American Cancer Society. Miss Beryl Roberts, formerly Director of Health Education in the Massachusetts Tuberculosis League, has been appointed Instructor in Health Education, and will be responsible for the development of the health education work in connection with the cancer program.

In addition to the basic postgraduate training leading to the Master and Doctor of Public Health degrees, the cancer control officers will receive special instruction through the coöperation of agencies in the state concerned with cancer diagnosis, treatment, research, and education.

Improving the Quality of Medical Care

The Training of Personnel *

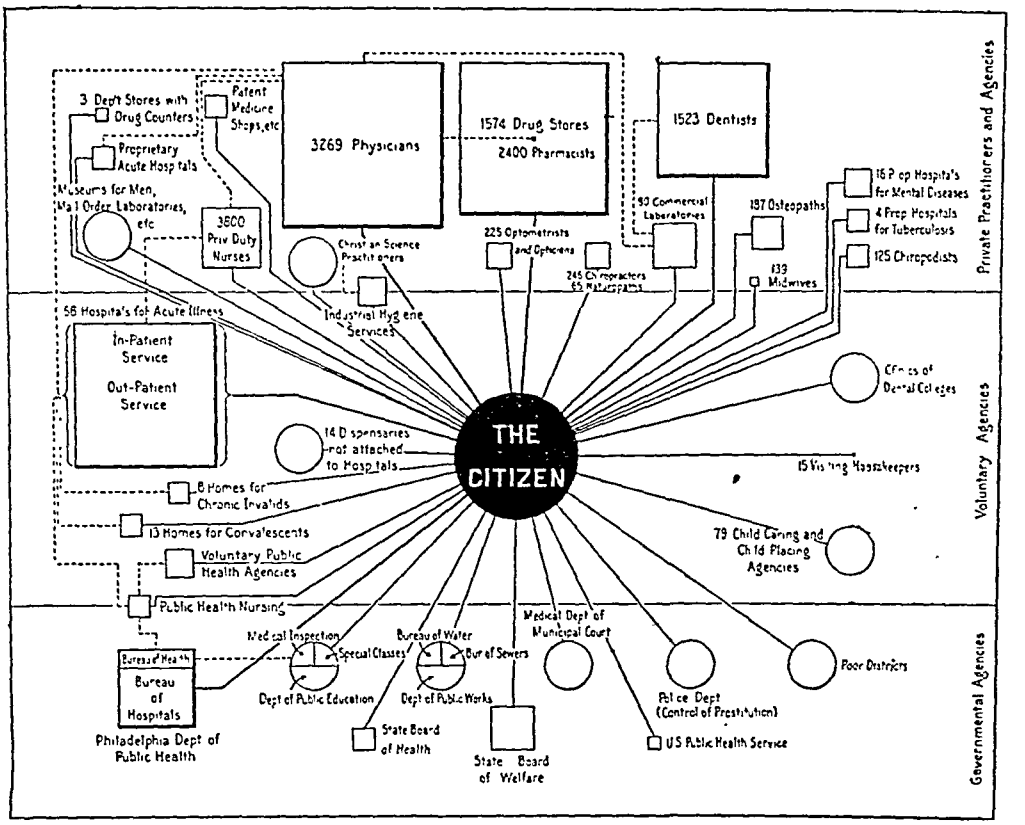
THOMAS D. DUBLIN, M.D., DR.P.H., F.A.P.H.A.

Executive Director, National Health Council, New York, N. Y., formerly Professor and Executive Officer, Department of Preventive Medicine and Community Health, Long Island College of Medicine

TRADITIONALLY, and in some quarters even today, the term "medical care" has been used synonymously with the services of a physician. During the last several generations, however, the accumulation of medical knowledge and skills has been so vast and the application of preventive, diagnostic, curative, and rehabilitative measures so complex that a radical alteration in this concept of medical care is inescapable.

If, for a moment, we limit our consideration to medical care within the hospital, recognizing that such institutional services represent only a limited, though vital, fraction of the total requirements of a modern community, I am reminded of a comparison made a few years ago by one of this country's outstanding clinicians and medical educators. As an illustration of the tremendous changes in medical practice which had taken place during his professional lifetime, he portrayed the contrast in the type of medical care received in the same hospital by two patients suffering from the same disease process, one treated in 1908, the other in 1938.[1]

In the first instance, the patient remained in the hospital for two weeks and the total record included two and a half written pages. The observations thus recorded represented the combined efforts of two physicians—the attending physician and the house officer—with assistance provided by one specialist, the pathologist-bacteriologist.



The second patient, cared for 30 years later, also suffered from heart disease and was still in bed after 19 weeks of hospital attention. At that time the total written record comprised 29 pages and represented the combined observations of 3 visiting physicians, 2 residents, 3 house officers, 10 specialists and 14 technicians; a total of 32 individuals. This enumeration, of course, does not take into account the additions in supporting personnel within the hospital made necessary by the rapid evolution of institutional medical services.

If we turn our attention to the broader panorama of complete health and medical services for the community, may I refer you to the accompanying chart (Figure 1) entitled "The Complexity of Medical Care," drawn from the final report, "Medical Care for the American People," of the Committee on the Costs of Medical Care.[2] This chart was prepared in the course of one of the studies made by that committee in Philadelphia in 1928. No one need be reminded that, in the 20 years which have elapsed, many other agencies and institutions have been added to those enumerated at that time, and many of those listed have expanded their resources and services.

Abundant additional evidence is available, as Franz Goldmann has recently stated, that the term "Medical Care"

* Presented before the Medical Care Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

FIGURE 1—From Medical Care for the American People, Final Report of the Committee on the Costs of Medical Care (Ray Lyman Wilbur, Chairman) *Publication No. 28,* the University of Chicago Press, 1932, Chicago, Ill.

THE COMPLEXITY OF MEDICAL CARE

This diagram shows the complex network of medical facilities in a large city. Many of the significant interrelations could not be depicted here. The area of each square indicates the relative costs to the citizens of Philadelphia in 1928 of various types of medical care. For items indicated by circles, data are unavailable.

must "be construed to mean all the personal services by members of the health professions, and all the clinic, hospital, and related facilities that are necessary to attain the highest level of health, prevent disease, cure or mitigate illness, and reduce, if not prevent, disability, economic insecurity, and dependency associated with illness . . . The various types of facilities and personal services essential to adequate care of the individual in health and sickness are so closely related to one another and so interdependent that they should be considered as an entity. Professional services for prevention and treatment must be combined if the war against disease, human suffering and poverty resulting from illness is to be waged successfully. The chain between illness and poverty must be broken, and organization of medical care in the widest sense of the term can go far toward achieving this objective."[3] It is on such a concept of medical care that I wish to base my discussion of some of the problems associated with the training of the personnel required to improve its quality.

According to the best figures available at the present time, approximately one million and a half persons are engaged as professional, technical, and other per-

sonnel in providing medical and allied services for the American people. Of these only one in seven, or perhaps one in ten, is a physician. Within the medical profession itself, in a short space of years, at least twenty-five separate specialties, I believe, have gained recognition; sixteen of these have been established with national qualifying boards. The training required for each of these branches of medical practice creates special problems, but a discussion of them at this time would not be germane.

In addition to the physician, the nurse, the dentist, and the pharmacist have long been identified with the provision of medical care. But what has not been appreciated sufficiently is that in the last quarter of a century a veritable host of indispensable coworkers have been brought into existence, and as Grant has pointed out, "There will not be adequate medical care . . . until auxiliary workers are provided in adequate numbers and their training and supervision well organized."[4] I know of no comprehensive listing of all these specialized skills which are now being called upon to assist and supplement the efforts of the physician. It is worthy of mention, however, that each year sees the formulation of minimum training and other requirements for additional groups of professional and semi-professional workers. As an example of what can and must be done on even a broader scale than at present, the Committee on Professional Education of this Association has accomplished an outstanding task by establishing basic qualifications for some fifteen separate categories within the public health field alone.[5]

If I concentrate my attention during the remainder of this discussion on the training of the physician, I do so because of my own greater familiarity with some of the problems in that area of education, and because of my firm belief that as the key individual in the medical care team the quality of service which the physician renders is immediately reflected in the performance of his associates. Also it cannot be overemphasized that despite its present-day mammoth proportions, medical care must always remain a highly personal service—one based upon intimate personal relationship of physician and patient. Even though a huge number of persons are now engaged in medical care, the physician occupies the hub position around which all others must rotate. It is his task to correlate, direct, and supervise the work of all others and it is to him the patient invariably turns for help and guidance in utilizing other skills.

The objective of any sound plan of training aimed at the improvement of medical care must be the preparation of the physician and his associates to meet adequately all of the health needs of the individual and of society. The "value," the "degree of excellence," or the "relative goodness"—that is, the quality—of the services they are to render is so insusceptible to accurate measurement that, at best, any indices of improvement thus far improvised are admittedly crude. It has been suggested that were we merely to augment the supply of physicians and other professional and technical personnel, a large share of our task could be accomplished. But even if one were to acknowledge glaring deficiencies in numbers, there is ample reason to believe that tremendous benefits would accrue were those workers now engaged in the health and medical field more equitably distributed, and were some effort made to improve the efficiency and utilization of available skills.

Several months ago, Dr. Alan Valentine, President of the University of Rochester, presenting a statement for nineteen university presidents, reported that for the last academic year (1947–1948) "The budgets of the seventy-

seven medical and basic science schools . . . exceed $43,000,000 and, generally speaking, this figure does not include costs of patient care in teaching hospitals, or plant maintenance, or general university administration, or research grants from foundations, industries and government"; and, continuing the quotation, "all things considered, I believe that medical schools now need about $40,000,000 more per year."[6] This sum of more than 80 million dollars, considered by the best qualified authorities as essential each year for the proper education of the approximately 23,000 students now enrolled in medical school, is admittedly small compared to what the American public spends annually on vitamin pills, jewelry, and recreation, and is less than is expended by those seeking admission to some of the major horse-racing establishments throughout the country. Nevertheless, at the present rate of expenditure, it costs the average medical school almost $9,000 to grant a single degree; the expenditures ranging through rather wide limits from slightly under $3,000 to somewhat more than $38,000. Of this amount, student tuition accounts for approximately 25 per cent.[7]

In his discussion, Dr. Valentine pointed out that the medical schools of the country are faced with a desperate economic crisis brought about by the difficulty of maintaining their current sources of income, plus the fact that to continue their present programs of teaching, the additional amounts needed year by year represent the income, at present interest rates, of an increased endowment of about one billion dollars. To this must be added the 200 million dollars which 55 schools are now seeking or estimate they need for replacement and improvement of physical plant and facilities. And yet, you will note, I have made no mention of the equally grave, though less well analyzed, financial requirements for the proper education of the other personnel essential to proper medical care.

It is possible that a satisfactory solution can be found through federal aid for professional education along such lines as those proposed by Senator Thomas of Utah in the last session of Congress (S. 2588, 80th Congress, 2nd Session). Until recently, however, the extension of tax support of medical education has been frowned upon in many quarters, even though more than one-third of our present graduates are receiving their degrees from institutions dependent primarily on governmental financing. It is fundamental that the needed support for the training of medical care personnel be forthcoming and yet, with costs and tuition rising rapidly there is sound basis for assessing the product which is now being turned out before jumping to the conclusion that all that is needed is more of the same.

It should be remembered also that since the turn of the century, the phenomenal addition of some 17 years to the life span of the American people has been shared by those entering the medical profession. Assuming that a physician begins practice at about age 30, his expectation of life at that age now amounts to almost 39 years.[8] Thus, his training and preparation for practice must furnish him with the basic equipment not only for the medical services he is called upon to render today, but for the type of professional endeavor in which he will be engaged many years hence. Moreover, we must provide postgraduate and continuing education of the physician of a quality at least equal to that which we demand of our undergraduate educational programs. Raymond Allen has expressed it most succinctly—"Any sound plan of medical education must embrace the entire educational process from childhood to retirement from practice."[9]

The period of medical progress which we now enjoy has been characterized by

the successful application of the great technical advances of the natural sciences, chemistry, physics, and biology, to the major disease processes to which man is heir. The focus of interest in the training of the physician has been drawn more and more to the mastery of isolated technological procedures and to the understanding of the structure and function of organs and systems. Though even greater triumphs lie immediately before us along this avenue of attack, in so proceeding "we have broken the human being into his component parts, even into individual cells, better to understand the workings of this marvelous living organism, only to become preoccupied with the fascination of the parts and to lose sight of the man. All too frequently the vital processes of synthesis and of understanding the working of the whole have been left for the graduate physician to accomplish as best he can in a later period of actual medical practice.

"We must not permit the brilliant accomplishments of the natural sciences to overshadow the fact that social conditions under which human beings live may contribute to the causation of disease, as well as to satisfactory treatment or prevention, just as much as physical, chemical, or biological factors. To be sure, the social sciences have only recently begun to make available to the physician highly refined techniques of study or scientific principles which can be applied readily to everyday problems. Too often has the physician been prone to overlook the vast contributions to health made by widespread public education, community sanitation, improved housing and working conditions, better general nutrition and many other social advances; and even at times, he has tended to minimize the importance of economic security of the family and of the group in the purchase of specific health and medical services."[10]

There are some of us who firmly believe that we stand today on the threshold of a new era of medical advancement—one in which the study of man as a social being, as well as a biological entity, may yield as great if not greater dividends in health than have been achieved through the less comprehensive approach of the past. Certainly, if prevention of illness and the promotion of health in the positive sense of the term are our objectives, such a perspective is an essential one.

We are strengthened in our conviction by the proposals for medical education of the future recommended in the report of the Goodenough Committee in Great Britain[11] and of the New York Academy of Medicine's Committee on Medicine in the Changing Order,[12] and by what is already apparent in some of our leading institutions of medical education.

Early this year a joint committee of the Association of American Medical Colleges and the American Association of Medical Social Workers published the findings of a three year study entitled "Widening Horizons in Medical Education"[13] in which current trends in teaching the social and other environmental factors in medicine are examined. As primitive and experimental as these efforts may be at the present time, they offer considerable encouragement to those who maintain that every physician must be prepared to direct his efforts in the control of tuberculosis, for example, through an attack upon social maladjustment as well as upon the tubercle bacillus; that he must include the public health nurse and the medical-social worker as well as the radiologist as integral members of his team, and that prevention of exposure and early case finding are infinitely more effective procedures than are pneumothorax or thoracoplasty.

To accomplish such a task, it will be necessary to utilize even more varied skills and greater resources than have commonly been employed in medical

education. No longer can medical care be provided in apparent isolation from the vast body of knowledge now being accumulated by the sociologist, the psychologist, the anthropologist, and the educator, to mention only a few. If anyone dares to minimize the contributions to medical care made thus far by the social scientists he might be reminded that the chemist, the physicist and the bacteriologist responded brilliantly when the physician brought to them for solution the challenging problems encountered in daily practice. Also, it is an interesting commentary on our times that many of the required resources exist in great abundance in the very environments in which our medical schools are located, and seek the opportunity to be of service in better fitting the future practitioner of medicine for his appointed tasks. In an experiment in which I have participated, it has been possible to weave effectively into an undergraduate program in preventive medicine the excellent physical resources and the expert skills of the staffs of four governmental agencies and more than a half dozen voluntary agencies actively engaged in community health work. Fifty years ago, the hospital and the medical school joined forces to great mutual advantage. On the one hand the medical educator could draw his student out of the lecture hall and the dissection room and enhance his theoretical training with practical experience at the bedside of the sick patient. In return the hospital and its staff received the intellectual stimulation and acquired the scientific methodology which only a close and continued association with an academic institution could provide. Today the public and private health agencies stand in the same position held by the hospital at the turn of the present century.

Better quality of medical care for the present, as well as the future, demands that the medical student as well as those preparing for membership in the associated professions be trained not only in the lecture hall, the laboratory, and the hospital; but in the clinic, the health center, the factory and workshop and, yes, even in the home, wherever the needs of the individual and the group require them to go. As the institution charged with the education of the physician, the medical school today thus has the unique opportunity and responsibility to serve as the necessary catalyst in raising the health status of the community. Through it a two-way channel can flow enriching the health agencies as it has already enriched the hospital, and in return its students will be better prepared to shoulder the responsibilities which later will be theirs. It is through such a pattern as this that we can best assure the proper training of personnel.

Before concluding this brief discussion, it is imperative that some reference be made to an indispensable link in the chain leading to improvement in the quality of medical care, for the future performance of the student is inseparably bound to the quality of his teacher. In keeping with the derivation of the term "doctor" and as set forth in his Hippocratic Oath, the physician has always recognized his fundamental obligation to transmit the fruits of his knowledge and experience to those who are to follow. Even today, a major share of the clinical teaching in the undergraduate curriculum as well as in the internship and residency periods is borne by the volunteer instructor, and modern medical education would not be possible but for the tremendous contributions in time and effort made by these members of the medical profession.

Nevertheless, since the turn of the present century there has been an accelerating need to supplement our teaching teams with a nucleus of well trained and inspired full-time and part-time instructors whose task it is to provide continuity and unity to our increasingly

complex educational pattern. In addition to such assignments this relatively small group of individuals has been largely responsible for many of the most significant advances in present-day medical practice and their devotion to research and teaching has served both as a guide and an inspiration to all students with whom they have contact. If we are to insure for the future the quality of medical care now known to be possible we must seek for such posts the best that our schools are now graduating; we must assure them the security which only a few now possess and we must provide the opportunity and encouragement to apply their talents to the larger problems of medicine now awaiting solution.

Disposal of Fluorescent Light Tubes

Industrial Lights, Division of Industrial Health, South Carolina State Board of Health, for January, 1949, calls attention to possible hazards from the indiscriminate breaking of fluorescent light tubes. Most types contain beryllium, which if it enters cuts or wounds, will delay or prevent healing and lead to chronic inflammation. The following precautions are suggested for those disposing of burned-out tubes:

1. Wear protective goggles and gloves at all times.
2. Break lamps out of doors (where possible) in waste disposal areas, or in ventilated hood and, to avoid unnecessary dust, within the waste container.
3. Where large numbers of tubes are disposed of, the operator should be required to wear a respirator approved by the U. S. Bureau of Mines for toxic dusts.
4. For ultimate disposal the broken lamps should be thrown into water or in a dump where they are not likely to be disturbed. Under no circumstances should the broken tubes be placed in an incinerator.
5. In situations where it is necessary to break the lamps indoors, it should be done in an isolated room and in a hood, so as to minimize escape of dusts. Sufficient exhaust ventilation should be supplied to the hood to provide an air intake of at least 125 linear feet per minute at the breathing level.
6. The division of industrial health of the state department of health should be consulted when doubt arises as to the best procedure.

Improving the Quality of Medical Care

Group Medical Practice *

DEAN A. CLARK, M.D., F.A.P.H.A.

Medical Director, Health Insurance Plan of Greater New York, New York, N. Y.

THE importance of training of personnel, regional planning, and sound administration in improving the quality of medical care cannot be sufficiently stressed. But while these three alone can accomplish wonders, they can be most effective when they are associated with group medical practice in the day-to-day delivery of health and medical services. Conversely, although group practice alone can greatly assist in the improvement of the quality of care, it can reach its full potential for this purpose only when it is intimately related to the other three factors. The intent of this paper, then, is to set forth the specific contribution which can be made by group medical practice in the combined effort to improve the quality of medical services.

Perhaps the most significant fact about what group practice can do toward improving quality is that its influence in that direction is inherent in group practice—it improves quality almost automatically, so to speak. Note well, however, the word "almost"; as we shall see later, pitfalls await group, as well as individual, practice, and these must be avoided if the inherent values of the group method are to be realized.

What is there about group medical practice that permits one to state so confidently that its influence is generally bound to be conducive to improved quality? To appreciate this, it is obviously necessary first to understand what is meant by the term "group practice" and something about how it operates. In general, we can accept any one of several recent definitions of the term, all of which stress five factors: (1) there are several physicians (three or more has been suggested as a minimum number by the Public Health Service); (2) these physicians are expert in more than one special field of medicine (three orthopedists associated with each other, for instance, would not be considered a "group" in the sense meant here); (3) the physicians are systematically associated, as in a partnership or as paid members of a staff of some organization (hospital, industrial firm, labor union, coöperative, etc.); (4) income from practice is pooled and, after overhead costs, reserves, and so on have been provided for, distributed among the physicians on some basis other than solely the amounts paid to the group by the particular patients of each; and (5) the physicians use in common professional facilities and assisting professional, technical, and clerical personnel.

There are, as most of you are well aware, many kinds of groups, for example, those which provide a general medical service as distinguished from those whose practice is mainly devoted to referred cases. Sources of income likewise vary, from those supported largely by fees-for-service paid by in-

* Presented before the Medical Care Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

dividual patients, to those chiefly dependent on a prepayment plan, an industrial or labor organization, or a health agency (official or voluntary) for their livelihood. For present purposes, the *kind* of group makes very little difference—although the "kind" does affect quality of service in many subtle and important ways. It is the *group method* itself in relation to quality of care which we are discussing. Nor are we greatly concerned here with the particular administrative structure involved, whether partnership, corporation, coöperative, and so on, although this, too, obviously can have great importance in considerations of quality. Here we shall emphasize more the factors common to virtually *all* kinds of medical groups, however they make their professional living.

It seems to me that group medical practice *per se* tends toward improving the quality of medical care because of the incentives it brings about in two separate, though intimately related, areas, namely the professional and the economic. In professional matters, the qualitative advantages of the group method arise from factors such as the following. The individual physician has easily available to him, in a medical group, the varied skills of his medical colleagues and associated personnel. He usually has access to technical facilities, such as laboratory, x-ray, and physical therapy equipment, vastly superior to what he as an individual could afford or could efficiently utilize. These associations stimulate and educate the physician as a member of a team. His specialized colleagues may be called in at a moment's notice; his daily work, in the nature of things, is constantly under the scrutiny of the other physicians of the group, senior and junior. In such circumstances, any man wants to do his best—and he expects their best from his associates. Other professional advantages work toward the same end A group may arrange systematically for free time for its individual members, whether for recreation or study. The young physician in a group may immediately exercise, under suitable supervision, the full range of his professional capacities instead of being obliged to wait, as is all too common in individual practice, for patients to accumulate while his hard-earned skills grow rusty. It is thus clear that the professional influences in a medical group provide an inducement to the improvement of the quality of service rendered by its physicians, individually and collectively.

In the economic area, the influences are no less conducive to our purpose. First, the group method, by its very character, makes for economies which aid rather than hinder professional quality. The ability of a group to obtain at relatively low cost to each individual physician, better technical equipment and personnel than its physicians could afford separately has already been mentioned. Additional economies are achieved by the fact that this equipment and personnel can be used to greater advantage by the group than by an individual physician. Many a general physician, for example, has in his office costly x-ray and physical therapy equipment which he can use but a few hours each day, but in a group such equipment can be kept busy to the limit of its capacity.

Second, physicians in group practice are apt to earn, whether because of the economies achieved or for other reasons, much higher net incomes, on the average, than those in individual practice. A recent study by "Medical Economics," for instance, showed that in 1947 whereas physicians in solo practice received an average gross income of approximately $18,000 and a net of $11,000, physicians in partnership or group practice averaged $27,000 gross and $16,500 net. While amounts of earning are obviously not necessarily

commensurate with quality of care, the possibility of a better living would seem bound, in the long run, to aid in attracting the better trained physician to group practice. The advantages of steady income and, in many groups, of a planned retirement system are other influences of the same character. The joy to a physician of being relieved of the tedious burden of business management, of hiring personnel, purchasing, setting and collecting fees, offered by a medical group through its business manager, is a third advantage in the economic area which not only attracts the best type of physician but leaves him free to devote his full time and energy to his professional work.

But, above all, from the standpoint of quality of care, the financial arrangements of group practice induce coöperative rather than competitive effort on the part of the physicians of a group. A healthy competitive element exists over the years, of course, in any group, because each physician wants to demonstrate his value to the group as a whole and thus his right to a larger share of the proceeds—even this is a stimulant for high quality in a physician's service. But for the daily work of rendering medical services, the economic as well as the professional incentives in group practice lead toward coöperation and, therefore, improved quality. For in a group, the good work done by any individual physician reflects credit on the whole group. Discredit for the whole group obviously results likewise from any physician's poor work. Therefore, all physicians of a group, if only from purely economic motives, are constantly stimulated to do good quality work themselves and, equally important, to urge their associates to attain the same ideal.

In most existing medical groups, the physician's share of the group's net income is based upon his competence and his general value to the group as a whole. These shares are usually not determined primarily by the number of patients seen or the number of services rendered by a given physician, although such matters may be taken into account. As a result, individual physicians in a group lose no income when they refer a patient to another physician, and have no financial incentive to "hold on" to a case personally. Rather, the financial interest of each physician is best served if the most thorough and satisfactory job possible is done for the patient by the group as a whole, so that the group as such may attract and keep a good clientele. Thus, the economic incentives of group practice encourage physicians to make use of the varied skills of their colleagues and of the group's laboratory and x-ray services for diagnosis and treatment as fully as may be medically desirable for the patient's benefit. Such teamwork medicine is of course the essence of group practice, and is obviously necessary to produce a high quality of care amid the complexities of modern medicine which cannot conceivably be grasped by any one physician alone. So we see that economic incentives for high quality, as powerful as the professional ones mentioned earlier, spring from the nature of the group method itself.

The value of group medical practice in improving the quality of medical care is not limited, however, to the positive advantages to be found within a medical group. It arises also in a negative sense, from the fact that group practice, and as far as can now be ascertained only group practice, will serve to correct many of the evils apparently inherent in the individual, competitive practice of medicine on a fee-for-service basis. These evils are in large part of recent origin and do not spring primarily from any malign intent on the part of the physician as a person but rather from the sane scientific advances which have made teamwork in medicine necessary and desirable. Some of these evils have

been referred to by implication in describing the advantages of group practice. The waste by duplication in individual offices of often inadequate but nevertheless costly technical equipment and associated personnel, rarely used to their fullest effectiveness, is one example. Another is the waste of the time and skill of the young physician in individual practice who must frequently spend much time in idleness before his talents can be fully utilized. The expensive equipment and highly skilled associated personnel and the long and costly training of the young physician, all of which are in part wasted in solo practice, are, of course, necessitated by the tremendous advances in medical science. All are too precious to waste. Group practice, especially in association with better training of personnel, regional planning, and sound administration can go far toward eliminating this waste.

But of all the evils of individual practice which the group method can eliminate, the most serious is the chaotic state of the relationships of the general practitioner and the various types of specialists with each other and the effects of these relationships upon the care of patients. Clearly, from the patient's point of view, he should be referred to the various types of specialists and provided with laboratory and x-ray examinations as frequently as necessary for the management of his case according to the best standards of scientific medicine, but no more so. Obviously, the exact optimum for such referrals is often impossible to determine in any given case but, over the long run, something very close to it can be achieved in a well organized medical group or on the wards of a teaching hospital. There is no doubt that the optimum can be and sometimes is achieved in solo practice, especially for relatively well educated and well-to-do patients. But the barriers to a proper use of teamwork in individual practice make attainment of this goal exceedingly difficult at best.

On the one hand, the physician in isolated practice may refer his patients to others too infrequently. He may fail to use others' services, for one thing, simply because his years in solo practice have so limited the horizons of his knowledge that he does not even realize that his patient might gain from special tests or consultants' opinions. He may hesitate, too, to refer a patient for consultation or other special service because of the cost to the patient. This may also be true in group practice, of course, but to a lesser extent because, in the first place, the group can control the fees for *all* the services the patient needs and can temper the wind when necessary, while the individual practitioner usually cannot greatly influence the fees set by the individual consultants to whom he refers patients. Second, it is the practice in many medical groups—and a good practice for improving quality—to make no charge for consultations; specialists' fees are charged only when the patient has been transferred to the specialist for continuing study or treatment.

But probably the strongest motive against utilizing referral services to full effectiveness in individual practice is the competitive element. In its crudest form, this means that a physician may not refer his patient to another physician for fear that he may "lose" his patient (and his fee) permanently to the second doctor. More subtly, it means that a physician may fear that by calling for frequent consultations he will undermine the patient's confidence in his own ability. He may believe that his reputation for self-reliance, broad medical knowledge and skill will suffer among his colleagues if he calls on others too much. Most of all, perhaps, he may fear that the consultant will find errors in his work and "show him up" to both the patient and the profession.

For all these reasons and for at least one more, namely, the sheer physical in-

convenience to the patient of going about from one office to another, making numerous appointments with varying periods of delay before seeing the different doctors, there is an inevitable tendency in individual practice not to employ the full medical team to the extent it should be used for realizing the full potential of modern medical service of high quality. The physician in solo practice, therefore, is often obliged to try to perform a range of service up to and sometimes beyond the limits of his technical capacity. This, of course, adversely affects the quality of service obtained by the patient and, in the long run, tends to produce in the physician a habit of superficial performance, trusting to luck and nature that his lack of thoroughness and of specialized knowledge will not cause errors resulting in serious disablement or death.

On the other hand, somewhat paradoxically, the physician in individual practice may under some circumstances refer his patients too *frequently* to other physicians. Here the practice of fee-splitting rears its ugly head. Fee-splitting, like the other evils mentioned, does not occur because of any desire of physicians to perpetuate a harmful practice, but arises almost inevitably out of the character of the individual practice system. I dare say it will continue, in spite of all the laws and professional pronouncements that can be devised, as long as this system is the prevalent method of practice. Here again, the basic reason is the advances in medical science which make specialization a necessity. One can hardly expect the general physician who has correctly diagnosed a case of appendicitis on a $10 house call not to feel that he deserves a lot of the credit for saving the patient's life and not to gaze at the surgeon's $200 or $300 fee with some envy. Moreover, one can understand that the specialist (particularly the young one, just starting in practice) in a fiercely competitive situation may yearn to reward tangibly the general physicians who most assist him in building up his practice by referring cases to him.

But it is not the act of splitting a fee that makes this practice an evil and an impediment to a high quality of medical care. It is, rather, the fact that the split is unknown to the patient and unregulated in amount and volume. Thus, the patient does not know, when he buys a pair of eyeglasses from an optician, for example, that part of what he pays may go back to the doctor who referred him to that optician. The same is true, of course, for x-rays, surgical procedures, and so on. The result of hidden fee-splitting is that if a sizeable split is in the offing the physician may be tempted to refer patients more frequently than is medically necessary and to send his cases to the doctor or laboratory or optician who gives the biggest kickback rather than the one professionally most competent to handle the case. The magnitude of the practice of fee-splitting may perhaps be gauged by the fact that more than 4,000 eye specialists—about one-half of those in the United States—were involved when the U. S. Department of Justice sought to stamp out rebates in the optical industry.

The utter futility, under our individual practice system, of expecting the medical profession to cope with this evil is illustrated by what occurred in New York City in the fee-splitting scandals under workmen's compensation a few years ago. Almost 2,800 physicians were charged with participation in the fee-splitting racket. One hundred and seventeen were definitely exonerated. More than 1,000 were definitely found to have been implicated. A few lost their licenses to practise medicine. But a diligent, personal search of the published records of all medical societies in New York fails to disclose a *single* instance in which any of the remaining 900 "definitely implicated" physicians were suspended

or expelled by a medical society. This is a commentary not only upon the durability of fee-splitting in the individual practice system, but also upon the ability of medical societies to set and maintain professional standards in general. It is in interesting contrast with the promptness and vigor displayed by medical societies in disciplining members who participate in group practice associated with prepayment plans for comprehensive medical care.

Group practice is sometimes considered to be a type of fee-splitting. This is *true* in the sense that a patient's payment is divided according to the group's internal administrative provisions, and does not go exclusively to the doctor or doctors who treated that particular patient. But group practice most emphatically is *not* fee-splitting in the sense that this open division of income among the physicians of a group is *never* a kickback paid for favors received. The patient knows all along that he is paying the group for his service, not an individual physician, and he fully expects the group to divide its income equitably among its members. So division of income by the group method completely eliminates the evils of the hidden kickback system and yet, at the same time, provides a distribution of income among general physicians and specialists more equitable than is possible in solo practice unless fees are split.

From what has been said up to now, you may think I believe that the group method not only is the best way to practise medicine of high quality, but also is without faults, pitfalls, or dangers of any kind. This is decidedly not the case. You will recall that earlier in this paper it was said that group practice was *almost* automatically conducive to a high quality of care. Now for the "almost." For one thing, physicians in group practice are still human beings and, like the rest of us, they do not always get along harmoniously, on either professional or economic grounds. The very closeness of their day-to-day relationship tends to emphasize any differences between the doctors in a group much more strongly than would be the case among the same men in 20 or 30 individual offices scattered all over town. This means, of course, that good methods of self-government, of administration, and of settling disputes are essential for the successful operation of any medical group.

Then, too, group practice can and sometimes does develop an impersonal attitude toward patients which may result in physicians dealing with people as case numbers or case "material" rather than as living persons with emotions, home difficulties, and business problems, living in a community. This is by no means inherent in the group method, but must be guarded against or corrected if it appears. One of the principal safeguards against such an impersonal attitude used by many groups is to make sure that each patient of the group has one—usually a general—physician whom he regards as his family doctor and who, in his turn, assumes real responsibility for the welfare of that particular patient at all times, or at least until the patient (or the doctor) decides he should be under the care of another physician.

Limitation on choice of physician sometimes makes both patients and physicians distrust group practice. It is sometimes claimed, indeed, that the competitive element in free-choice individual practice is a stimulus toward improved quality in the service rendered by the competing physicians. This seems at best a dubious contention, for the untrained "customer" is exceedingly poorly equipped to judge the quality of a physician's service, and may likely be influenced mostly by factors having little to do with quality. For shoes or ice boxes or even politicians the public may have some basis to make a judgment,

but how can it evaluate a surgeon's skill or a bacteriologist's competence? On the other hand, the kind of competition found in individual practice places an emphasis on *quantity* of service and upon the money received for it that certainly distracts the doctor's attention from its qualitative aspects, to put it mildly. Healthy competition exists within medical groups, as already pointed out. Vigorous competition often exists between two or more medical groups also. So group practice can make use of the good features of competition, which are conducive to high quality, while avoiding most of the bad features, which do it harm.

To return to choice of physician, choice naturally *is* limited within any one group, although patients may, of course, leave the group entirely if they wish, and the choice is in any case much less limited than that of the patient in the ward or outpatient department of a voluntary or public hospital. Most groups encourage their patients to select freely among the physicians who are competent in the particular field of service they require. Groups also permit patients to change physicians if they wish. On the positive side, a group is in an excellent position to guide a patient intelligently in the choice of the physician best suited to his needs. Such guidance seems usually to be gratefully accepted by the patient, if it is given tactfully and thoughtfully.

Some groups have irritated their patients by a confusing welter of administrative detail, numerous records to be made out, involved appointment systems to be dealt with, complicated procedures to be followed, puzzling mazes of corridors, examining rooms, laboratories, and so on. These are real danger points, especially in a large group, but most of them can usually be avoided by skillful and patient administrative effort.

Another frequent charge is that, in group practice, physicians are apt to use the readily accessible consulting, laboratory, and x-ray services too freely —in other words, to show a tendency to give every patient "the works," whether he needs it or not, often at extravagant expense. This obviously can happen. But studies of numerous groups in actual operation indicate that it happens infrequently and need not happen at all. Indeed, an interesting study made two years ago by the Pennsylvania Hospital Association showed that in several sample private groups, patients' total fees for accessory services were considerably less than they would have been for the same services procured through solo practitioners, and in several instances less than the fees would have been in voluntary hospital outpatient departments. As a matter of fact, a well administered group can control excessive use of such services far better than can individual practitioners.

Finally, it is sometimes said that physicians in medical groups tend to stick too close to their building, being reluctant to make home visits, go to rural areas, etc. This also can happen and has happened, particularly in the so-called "reference" groups. Again, however, this weakness is not inherent in the group method. Many groups diligently serve the people of their communities at home or wherever else they need to be cared for, and some have successfully established part- or full-time outposts in small towns or rural areas which were so small or so poor that they had for years been unable to support an individual practitioner. But because the outpost doctor also could spend part of his time in the group's center and could send patients there for complicated problems, the group could easily afford to serve the little community without mileage fees or hurried, long ambulance trips.

It can be seen, therefore, that there are indeed problems to be solved and many dangers to be avoided if group

medical practice is to provide the high quality of medical care it is potentially capable of rendering. Yet, none of these appears to be so intimately a part of the group method that it cannot be successfully attacked if patience, intelligence, and energy are devoted to it.

In summary, group medical practice, particularly in combination with good personnel training, regional planning, and sound administration, offers an excellent method of improving the quality of medical care because of the many professional and economic incentives it affords which lead to medicine of a high quality. If thoughtful preparation, skillful administration, and a spirit sympathetic with patients' needs go into the development of group practice, we may expect to see it continue to spread and expand and to aid mightily toward the great objective of making the best in modern medical service accessible to all the American people.

American Public Health Association Resolutions

An Editorial from the J.A.M.A.

"On page 159 of this issue appear two resolutions adopted at the annual meeting, held in Boston in November 1948, of the American Public Health Association.

"One resolution deals with coöperation in the school health program and calls on the National Education Association and the American Medical Association to coöperate with the American Public Health Association and other groups in approving the principle of coöperative planning of health programs which involve children of school age. This resolution expresses the long declared and well implemented policy of the American Medical Association which began with the first meeting of the Association in 1847 and has been continuously a guiding principle in its policy. Since 1911, the American Medical Association and the National Education Association have coöperated through a Joint Committee on Health Problems in Education. Frequent symposiums on health of school children have been held at American Medical Association meetings. The Association has an active program of coöperation with educational agencies for better national health achieved through better health education and school health programs.

"The second resolution likewise coincides with the views of physicians often expressed, that the present system of allotting state aid to schools and school districts in part on the basis of average daily attendance is pernicious, conducive to attendance by children who are harming themselves and menacing others and a temptation to the violation of sound sanitary principles for the school in increasing or maintaining subsidies.

"The nation's leading public health organization does well to invite coöperation of the medical profession. Successful public health workers in official and voluntary agencies have long since learned that a coöperative medical profession is their strongest and best ally, but this idea has not seemed to permeate to certain leaders of the public health profession.

"The two resolutions calling on the American Medical Association for coöperation represent but two in the many areas of agreement between the associations. Others include the movement for county health unit coverage, the fight for universal pasteurization, the better training of public health personnel with a consequent improvement in salaries and tenure, the extension of the merit system in public health official agencies, the advance of medical research and the perennial battle against quackery. The organizations representing the medical profession and the public health profession should face the public united in their areas of agreement, especially since there is a large overlapping in membership."

J.A.M.A. 139, 3:157 (Jan. 15), 1949

Improving the Quality of Medical Care

Regionalization of Hospitals *

ALBERT D. KAISER, M.D., F.A.P.H.A.

Health Officer, City Health Department, and Executive Director, Council of Rochester Regional Hospitals, Rochester, N. Y.

EXPERIENCE has shown that small communities do not ordinarily have in their midst the trained persons and educational resources to enable hospital and medical practice to attain the development reached in large medical centers. Through a grant from the Commonwealth Fund, whose Division of Rural Hospitals is concerned with the building and developing of general hospitals in small communities, an experiment was set up to work out a method whereby the existing resources of small communities can be supplemented and integrated into a close working relationship among themselves and with a large community functioning as a regional medical center.

The regional hospital plan was set up as an experiment and a demonstration in a voluntary association of hospitals and their medical staffs, known as the Council of Rochester Regional Hospitals. The problems of medical care of patients in the hospital are given primary consideration during the first few years of the Council's organization. It is anticipated that the principles of regional administration developed in connection with hospitals will apply also to public health and to the broader aspects of medical care. The economic aspect of medical care as related to payment for service is entirely outside of the scope of the Council program.

The Council has a basic policy or "charter" which is set forth in its agreement with the Commonwealth Fund. The 5 points of basic policy are:

A. Financial aid and planning for rational distribution of adequate hospital facilities throughout the region.

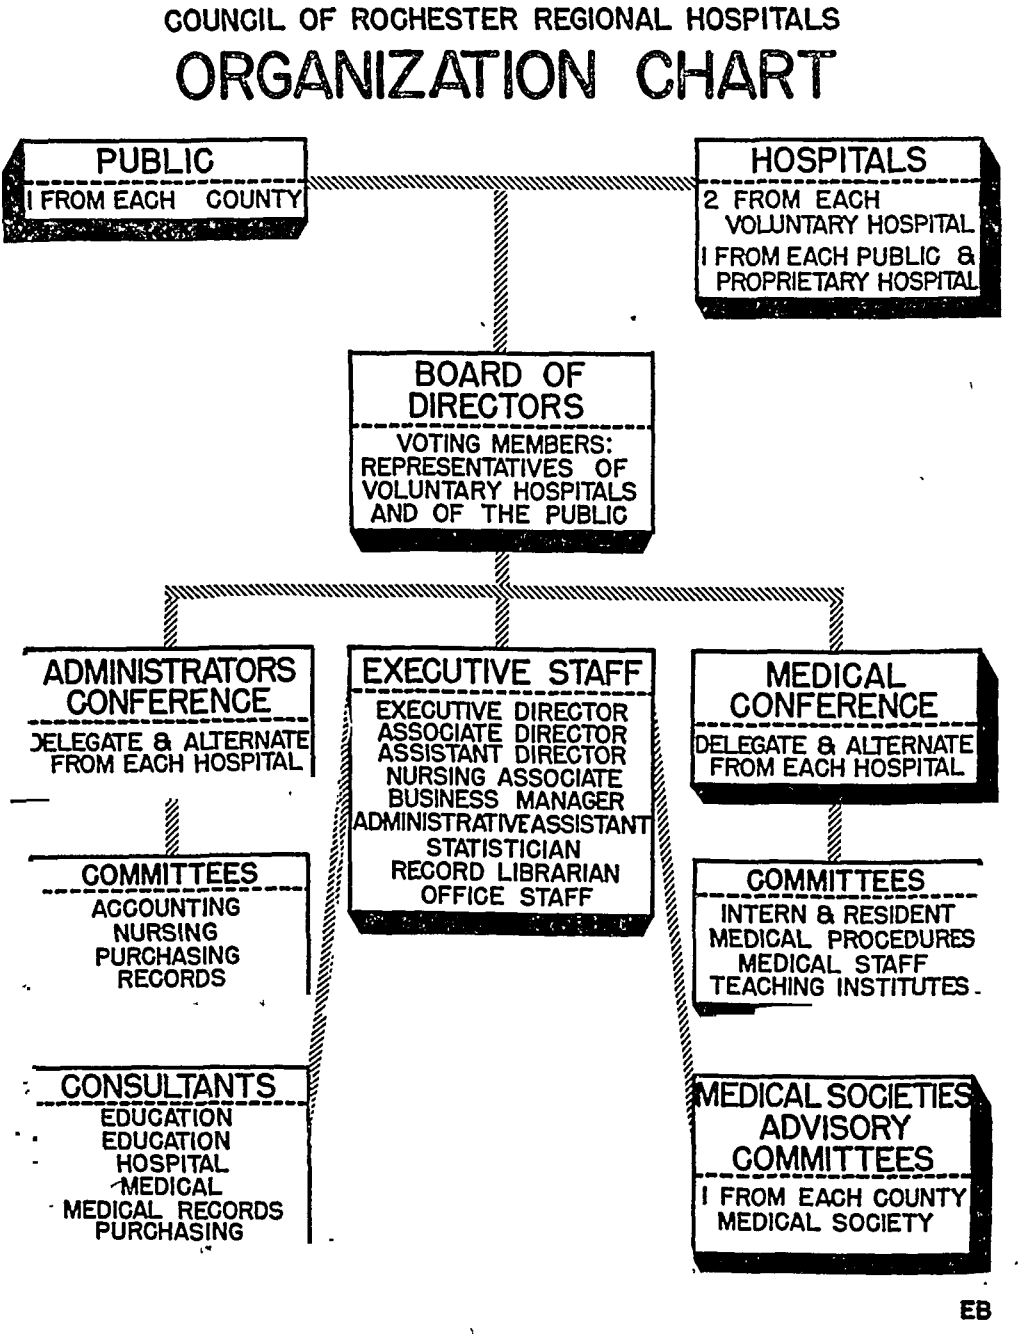
B. The promulgation of approved procedures in all departments of hospital organization and operation.

C. The development of such joint administrative services as may be considered desirable and practicable.

D. The development of consultation services in clinical and laboratory medicine, and in institutional administration.

E. The organization and administration of a continuous educational program for physicians, dentists and hospital personnel with emphasis on postgraduate study.

To provide funds for the plan the Commonwealth Fund made available a sum of $275,000 per year for 5 years. The annual contribution from Rochester funds is $10,000. Of this total an annual sum of $200,000 is allocated to capital improvement of small community hospitals, and $85,000 to education, advisory services, and administration. The grant is assured for a period of 5 years. At the end of that time, it is provided that the contract may be renewed with the expectation that the members of the Council, during the second period, will gradually assume a large part of the cost of their organization and the services it renders.



The region includes 11 counties in the trading area of Rochester. It contains a medical school, 6 urban voluntary hospitals, and 26 general hospitals

* Presented before the Medical Care Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

outside of Rochester. Full membership is limited to community hospitals owned and operated by unofficial, nonprofit associations and providing general care for acute illness. Associate membership with nonvoting representation on the governing and advisory bodies and with all benefits except grants for capital improvement is offered to governmental hospitals and to hospitals operated for profit.

ORGANIZATION

A Board of Directors, mostly laymen, guides the affairs and makes the policies for the Council. It is composed of two delegates from the governing board of each member hospital, and one

lay public representative from each county who has no direct connection with any hospital.

Two delegate bodies advise the Board of Directors, namely the Administrator's Conference and the Medical Conference. The Administrator's Conference, composed of the hospital administrators and their alternates, serves as a forum for the exchange of information on hospital administration. It also studies methods to solve common problems, and recommends policies and projects for the consideration of the board. The Medical Conference has a similar purpose as related to medical practice and problems centering around hospitals. It is composed of one physician and one alternate physician elected by the medical staff of each member hospital, and a representative of each county medical society.

The executive staff is made up of the executive director, a physician who serves on a part-time basis, a full-time associate director, who is also a physician, an administrative assistant, a business manager, a director of nurses (part-time), a public relations director, and secretarial assistants. The executive staff is assisted by consultants in hospital administration, medical education, public health, nursing services, accounting, and purchasing services.

In order to obtain broad interest in the regional medical experiment, several committees emanating from the Board of Directors, Administrator's Conference, and Medical Conference are actively engaged in promoting studies and improvements in their respective fields. These committees initiate their own activities and are assisted in their work by members of the executive staff. The numerous meetings conducted by the committees and the larger conferences have brought the men and women of the rural hospitals into friendly and helpful relationships with medical and lay members of the urban hospitals. This accomplishment has contributed immeasurably to the success of the regional experiment.

HOSPITAL SURVEY

Before offering the member hospitals services concerned with the administration and with professional activities, hospital surveys were conducted by the executive staff. These were primarily concerned with the operation of the hospital, organization, and activities of the governing board and medical staff, and thorough investigation of the functioning of the hospital, department by department. Such surveys were made at the request of the governing board and findings and recommendations were reported only to the board of the hospital concerned. The completed surveys revealed the deficiencies that existed in each member hospital and directed the program that was outlined to improve the services that might assure better medical care.

These surveys revealed not only the inadequacies of the physical plant and certain types of equipment, but it brought to light administrative and professional practices in a number of instances that were not in accord with accepted hospital operation. For example, it was found that medical records, which should be a source of information of the quality of medical care received in the hospital, in many of the member hospitals were inadequate or not used because of: failure of physicians to complete medical records accurately, completely, and within a reasonable length of time; lack of medical record librarians trained to keep, classify and index records properly, and to develop useful statistics from them; and widely varying record systems and nomenclatures. A statistical study of deaths recorded in the hospitals from various causes showed that there was considerable difference in the death rates for the same condition in neighbor-

ing hospitals. Where this occurred over a 3 year period it could be assumed that the professional care, medical and nursing, could well have played a part.

Laboratory and x-ray facilities likewise were not equally satisfactory. These variations were generally due to lack of trained personnel or in some instances to inadequate equipment. Staff organization was given little or no consideration in a few hospitals while in others it was operating in a most successful manner. The information gained from the surveys was transmitted to the directors and staff of each hospital with the hope that some effort would be made to rectify these deficiencies.

DIFFICULTIES ENCOUNTERED

It should be pointed out that any effort to improve medical care in which a central administrative group is involved arouses some suspicion on the part of its constituent members. This was true not only for some of the physicians actively interested in area hospitals, but for some of the hospital administrators. A feeling of insecurity was evident and a fear that local autonomy would be threatened was voiced. As the voluntary, rather than compulsory participation, became thoroughly understood, confidence in the Council and in its objectives was gradually established. Today, after two years of operation, all fear of domination and control has been dispelled and almost unanimous coöperation is the outstanding feature of the Hospital Council's activities.

PLAN OF PROCEDURE — HOSPITAL ADMINISTRATION

Surveys of hospitals and evaluation of existing services provided the blueprints for action that might assist in improving the medical care given in area hospitals. It was evident to those charged with the execution of the experiment that no phase of hospital operation could be overlooked and that all personnel, including hospital boards, administrators, professional staff, and others should be reached in a program to stimulate them to greater awareness of their responsibilities. Simultaneously, efforts were made to reach all groups associated with the operation of the hospital.

Hospital administration in the small hospital varies greatly, depending upon the competency of the administrator. Early in the regional experiment a college credit course in hospital administration was given at the University of Rochester, in which prominent hospital administrators participated. A second, more advanced course in hospital administration was given a year later at the request of those who took the first course. Assistance was given to area hospitals in various administrative departments such as accounting, hospital records, reports, statistics, purchasing, personnel service, nursing and other related services. Employees of the small hospitals were given fellowships for specialized training or consultants were sent to the small hospitals from the large urban hospitals. Institutes were conducted in Rochester for accountants and bookkeepers. An institute for Medical Record Librarians was highly successful and paved the way for a marked improvement in the medical records of area hospitals. Funds available for educational purposes were used in providing fellowships for selected employees in institutions outside of the Rochester area. Significant changes and improvements were brought about in the important field of hospital administration.

PROFESSIONAL ACTIVITIES

Among the first activities undertaken by the medical group was the appointment of a committee of doctors to set up a manual of medical procedures to

guide the individual physician in the performance of his routine duties, both in the interest of the patient's welfare and for the professional reputation of the hospital. This involved a consideration of the minimum qualifications for granting hospital privileges in such fields as surgery, obstetrics, medicine, radiology, and anesthesiology. These model policies are not obligatory but are stimulating staff members to elevate their standards.

To offer the doctor practising in the rural areas assistance from the medical center presents some difficulties. In some instances physicians resent the inference that they need instruction or guidance in their daily problems, while in other situations the fear exists that physicians associated with urban hospitals coming to the small hospital will threaten the relationship that exists between physician and patient. Nevertheless, it is gratifying that the medical staffs of all of the member hospitals invited professional educational assistance from the hospitals in the medical center.

In any experiment conducted to improve the character of medical care in an area it is essential to have reasonably accurate information on the death rates where the kind of care rendered may have played a part. Such a study was prepared by tabulating the deaths in the various hospital areas in the three years prior to the regional experiment. Ultimately, similar studies will be made on the death rates in the same areas to determine what, if any, effect the new educational facilities may have exerted on the medical practice of each community. Information made available to each hospital staff on such diseases as appendicitis, herniotomy, diabetes, prematurity, accidents, etc., brought directly to the attention of each physician how his hospital area compares with comparable institutions in the management of the common medical and surgical procedures.

Obviously the hospital area with a death rate charged to appendicitis that is twice as high as that of a neighboring hospital area should be stimulated to have its staff investigate the diagnostic and surgical procedures practised in that hospital area. Similarly the hospital area in which the death rate of infants under one year of age is twice as high as in a neighboring area, invites a thorough analysis of hospital facilities for the care of the new-born and especially the organization for the care and follow-up of the premature baby. Making these indisputable data available to each hospital staff points out the desirability of improving certain professional services in the hospital and in the community.

The establishment of clinical conferences in the small hospitals was gratefully accepted. Through a medical committee of the Regional Council, monthly staff conferences were arranged in each of the rural hospitals. Eminent physicians in all fields of practice were sent from the medical center to the small hospitals. The visiting clinician spends half a day with the small hospital staff to discuss a number of problem cases and then makes ward rounds with some or all of the staff members. The success of these clinical conferences and the good will established between the small and large hospitals has more than justified this procedure.

The coöperation of physicians with teaching ability has been most helpful to the program. Such men are very willing to participate, although distances of 100 miles or more are often involved and travel conditions throughout the region during the winter months are far from pleasant.

POSTGRADUATE COURSES

During the early part of the Regional Hospital Council's existence, staff discussions centered about plans for accelerating postgraduate medical educational

opportunities. The program of clinical conferences was a definite success. Seeking other means to meet the needs of physicians outside of the city, the staff turned to "refresher" courses. Inasmuch as the busy doctor in the small town or in the country finds it difficult to leave his practice for long periods, short courses of one week's duration were provided in the larger hospitals and at the Medical School in Rochester. Competent instruction was provided and material of immediate value to general practitioners was presented. The courses were designed to combine clinical and didactic teaching, with an opportunity to discuss problems with persons well qualified in the field.

The content of the courses was to be centered around common problems and procedures in diagnosis and treatment. Thus far, 6 courses have been conducted, with an average attendance of 20 physicians, most of whom came from the hospitals outside of Rochester. The courses have served not only as an educational contribution to those who attended, but strengthened the friendly relations between the physicians living in the smaller communities and the physicians, many of whom are specialists, identified with the hospitals in the medical center. This type of postgraduate teaching will be continued and perhaps extended into new fields.

INTERN AND RESIDENT ROTATION

None of the area hospitals except the large institutions had a resident staff. Because a resident staff is of great and obvious value to the hospital, the Regional Council undertook a program of rotation of a series of interns and residents from the large city hospitals to the smaller hospitals for periods of from 2 to 3 months. This program was approved by the Council on Medical Education and Hospitals of the American Medical Association. The rotation of interns or residents has been in progress for 2 years in 1 hospital and for a shorter period in 3 other hospitals. This rotation of house staff from the parent hospital in the medical center to the small hospitals of about 100 beds has proved beneficial to the area hospital. Difficulties naturally arise on the part of both parent and recipient institution but these obstacles are gradually being overcome. The experience gained by the intern or resident in the small hospital has proved valuable. A better understanding of the problems of the rural area is obtained by the young doctor, and the presence of a resident physician in a small hospital stimulates the visiting staff to a keener interest in patient care. Improvement in hospital records is apparent, autopsies have increased and routine staff rounds have been instituted. The parent hospital supervises the training of the resident while in the small hospital, and a committee of the rural hospital is held responsible for the proper use of the rotating intern or resident. Extension of this program to more rural hospitals and greater participation on the part of the small hospital staffs should ultimately lead to better hospital practices.

NURSING SERVICES

In the field of nursing the Council has a number of direct interests. Its nursing director has concerned herself primarily with the quality of nursing care in the region, while other staff members, through assistance in student nurse recruitment campaigns, advisory services in connection with the training of auxiliary workers, and studies of nursing hours, have been active in increasing the quantity of nursing care.

The Council has established 3 projects in the field of postgraduate education; postgraduate fellowships for members of the nursing staffs of member hospitals; regionalized nurses' meetings of a professional nature; and expansion of the Department of Nursing Education

at the University of Rochester. In addition to the direct services which have been made available to the nursing divisions of the member hospitals, studies are being conducted on patterns of nursing care in which subsidiary workers assume a much more important role.

CONSULTATION SERVICES

In the fields of radiology, pathology, and anesthesiology, not all of the small hospitals were properly staffed. Where possible, consulting services emanating from the medical center are offered in these fields. Significant assistance has been provided by the Council through consulting service in developing radiology departments, determining needs, and advising as to equipment needed. In one hospital, where this was done in 1947, a saving of $6,000 was realized over the amount that the hospital had planned to pay for equipment. The saving resulted from definite recommendations as to equipment required to meet the hospital's needs, and the elimination of unnecessary items which the hospital had planned to buy.

JOINT PURCHASING SERVICE

From its beginning, the Council sensed that organization of hospitals into a group would make possible joint buying at substantial savings. The subject of joint purchasing was studied thoroughly by the Purchasing Committee of the Administrator's Conference, and after a number of surveys and adequate discussion, the Administrator's Conference and the Board decided to embark on a program of this kind. To facilitate this program, member hospitals agreed on specifications and standards for certain items such as linens, and planned that a single order representing the needs of all participating hospitals for a 6 or 12 month period be placed at one time. In this connection it is hoped that inventory and budgetary practices in the smaller hospitals will be improved. Under the present system there is no compulsion to purchase through the Council. Hospitals may make such purchases as they choose through the Council and others wherever they like. The Council acts simply as a central purchasing office, receiving orders from its members and turning them over to suppliers for shipment directly to the hospitals. The Council pays cash as bills come in, in turn billing the hospital receiving the goods. The participating hospitals can make substantial savings by utilization of this service.

REGIONAL BLOOD BANK

In some of the meetings of the medical conference, composed of staff representatives of each of the member hospitals, attention was called to the fact that blood to be used for transfusions was not always available and rare types of blood were difficult to obtain when needed. Consequently blood therapy was not utilized in indicated cases as frequently as in larger hospitals where blood banks could be maintained. In cooperation with the large Rochester hospitals already operating separate blood banks it was decided to develop a regional blood bank to serve all of the hospitals in the Rochester Region. Utilizing the studies and plans made by the staff representatives of the member hospitals and with the support of the 11 county medical societies, a plan was finally evolved for the operation of such a bank. At this stage the American Red Cross expressed interest in establishing regional blood banks in various parts of the country and considered the Rochester region an excellent place in which to initiate its program. The Red Cross accepted full administrative and financial responsibility for this regional blood program and in a short time brought to reality what had been a hope on the part of physicians and hospital people throughout the Council's region for some time. For about a year this regional

bank has been operating in a most satisfactory manner and thereby offers patients, treated in any of the area hospitals, adequate amounts of blood wherever indicated. This service has been greatly appreciated, especially by the communities never before served in this way.

PLACEMENT OF PHYSICIANS

With full knowledge of the personnel needs in the region, it has been possible to place young physicians in areas where well trained physicians are urgently required. As the experiment develops and the advantages of rural practice under more favorable hospital conditions become known to young doctors, it is hoped that the placement of physicians will be of assistance in the needy areas.

Insufficient time has elapsed to evaluate the efforts to assist the rural physicians in their home and hospital practice. It is quite clear to the executive staff of the Council that the practising physician in many small communities has rendered excellent medical care, in and out of the hospital. The advantages and facilities are generally inferior to those of the urban area and difficulties arise which cannot be easily overcome. Some of these deficiencies can be corrected by the small hospitals themselves, others can be solved by closer association with the medical center.

The urban hospitals and the medical school have the facilities and the personnel to assist the small institutions within a certain area if they are willing to make them available. It is equally important for the small hospitals to seek these services. If an effective voluntary relationship can be established it will not only assure better small hospital functioning but also will improve medical care in the local community.

New Mental Health Project in Wellesley, Mass.

It has been announced that, under the combined auspices of Harvard School of Public Health, Harvard Medical School, Harvard Department of Social Relations, Massachusetts General Hospital, and the Wellesley Community Mental Health Committee, a mental hygiene combined service-research organization has been established in Wellesley with funds from the Grant Foundation for a five year period. Dr. Erich Lindemann, Lecturer on Mental Health in the Harvard Department of Public Health Practice, will direct the program and supervise two field teams, one a service team composed of two psychiatrists, a social worker and a clinical psychologist, and a research team composed of a social scientist and a social psychologist. The Wellesley project is being initiated as a community health service, accompanied by a prolonged study of the effect of social relationships in the community, with the family as the study unit.

Improving the Quality of Medical Care

Sound Principles of Administration *

EDWIN F. DAILY, M.D., F.A.P.H.A.

Director, Division of Health Services, U. S. Children's Bureau, Social Security Administration, Federal Security Agency, Washington, D. C.

IN general, the principles of administration relating to quality of care are equally applicable to any medical care program, whether governmental or nongovernmental, tax supported, or supported by prepayment contributions.

The quality of medical care is primarily of importance to the recipients of services—the patients. It is in their interests I speak, and it is their wishes I am trying to express, rather than considering principles of administration in the abstract.

In order to emphasize the importance of the individuals to be served, I will present some of the principles of administration which I believe most individuals would desire in any medical care program.

A. THE SCOPE OF THE PLAN

1. I would want the plan to provide all professional and auxiliary services, hospital, and convalescent home care that I might need and that could be made available. I would not want anything to do with a plan that is concerned only with assuring payment to surgeons for their operations or providing only fragments of the services required.

B. THE PERSONNEL

1. I would want the administrative staff and all professional personnel of my medical care plan to be concerned always with the promotion of positive health, the prevention of illness and disability, as well as the treatment of disease and rehabilitation, for each and every one of us covered by the plan.

2. I would wish to have my medical care plan provide, or pay, for services rendered only by professional personnel recognized as competent in their respective fields. I would hope that my medical care plan would prevent me, if possible, from seeking professional help from individuals who are not competent to provide it.

3. I would wish that those persons who set standards for professional personnel would consider it important that the physicians be as much concerned with environmental and social causes of illness as with their biological and other causes.

4. I would like to have my medical care plan provide physicians and other personnel who are as interested in the long-time treatment of my child with cerebral palsy as they are interested in the dramatic response I made to treatment with a new antibiotic.

5. I would wish the physicians to be selected from among those who would *treat me at all times as an individual*, giving me as much personal attention as they would wish for a member of their own family. I would not like to be "Case No. 329," and be given a brush-off as one of 50 patients being seen that morning.

6. I would want to see my physician *in an attractive office or clinic*, where

* Presented before the Medical Care Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

there are comfortable chairs, because I dislike basements of courthouses and hard benches.

7. I would like my office visits to be by appointment, for I dislike waiting for hours on a hard bench *or* in a comfortable chair.

8. I would like to be able to change my physician if I became dissatisfied with him or if he thought I would do better under the care of another physician.

9. I would wish my medical care plan to afford its professional personnel, wherever feasible, opportunities for working in groups—with easily accessible diagnostic equipment they may need—in order that they may easily consult with each other, and in order that I may not need to go from one place to another for a series of consultations or laboratory tests.

10. I would want to know how, when, and where I could get medical care in an emergency, whether such care is required at home, office, or hospital.

11. And, since what is good medical care today may not be good enough a few years from now, I would wish to have the personnel in my medical care plan have regular opportunities for postgraduate training and to be continually considering ways and means of bringing to us—the patients—the most recently acquired knowledge in this great and complex field of human endeavor.

C. THE FACILITIES

1. I would wish to have my hospital care only in institutions which meet national standards of performance, and my medical care plan should not provide care in hospitals which do not meet such standards.

D. THE ADMINISTRATIVE MACHINERY

1. I would not want to be told at any time that I was not eligible for care because of the place of my legal residence, or because my skin was not white, or because my income was up or down during a given year.

2. I would not wish to have red tape, or tape of any other color, delay my obtaining any services I need under my medical care plan.

3. I would want my taxes or prepayment contribution to cover all costs of all services provided, and I would not want the physicians or hospitals to ask me for more money because my case was unusual, or because they did not think the plan paid them enough.

4. I would want the method of payment to physicians and hospitals to be of a type that would prevent the possibility of financial considerations influencing the clinical decisions of the physicians or hospitals.

5. I would want the administrator of the plan and his staff to be fully competent to develop the best medical care plan possible, and to improve it year by year on the basis of experience. I would want this staff to be selected on the basis of merit alone, to serve only the best interests of the community and not the selfish interests of any special group.

6. I would want a group representing those of us served by the plan, and those providing services, to be given ample opportunity, at regular intervals, to confer with the administrator and his staff and to express our viewpoints fully.

7. I would like to have an impartial appeal board established to hear my complaints about the plan, or complaints of the professional staff providing services.

8. And last, I would like to have the amounts of money paid the administrator and his staff, and the professional personnel, high enough to attract and hold in rural or urban areas the best people available, and to have working conditions and other factors conducive to their deriving satisfaction from their work. I would not want bargain counter medical care.

I have stated no new principles. We

have all talked about one or more of them on many occasions. It may be new to have them presented together, and from the viewpoint of the patient. At this time, when many public and voluntary medical care programs are developing in this country, it might be of interest to the administrator and the public to evaluate each program on the basis of these principles.

Blackwell Citations to 12 Women

On January 23, 12 women distinguished in medicine received Elizabeth Blackwell centennial citations from Hobart and William Smith Colleges, Geneva, N. Y. This event celebrated the 100th anniversary of the graduation from the medical department of what is now Hobart College, of Elizabeth Blackwell, the first woman in the world to receive the M.D. degree, and the founder of the New York Infirmary for Women and Children for the training of women physicians.

The women receiving the citations were nominated by the deans of American and Canadian medical schools, by several professional bodies, and by other medical leaders. They are:

Gerty T. Cori, Research Associate, Washington University School of Medicine, St. Louis, Mo., third woman to receive Nobel Prize in Science. For work in biochemistry and pharmacology.

Margaret D. Craighill, Chief of Service in charge of medical care of women veterans, Winter Veterans Administration Hospital (Menninger Psychiatric Clinic), Topeka, Kan. For military medicine.

Martha May Eliot, Associate Chief, U. S. Children's Bureau. First woman president of the American Public Health Association. For public health.

Therese Bertrand Fontaine, Paris, France. First French woman medecin des hopitaux.

Alice Hamilton, Consultant on industrial toxicology for U. S. Department of Labor and U. S. Public Health Service. First woman appointed to medical faculty at Harvard. For industrial medicine.

Elise S. L'Esperance, assistant professor, Department of Preventive Medicine, Cornell University Medical College; President, American Medical Women's Association. First woman to hold rank of Assistant Professor in Cornell University Medical College. Planned and established first Cancer Prevention Clinic in 1937. For work in cancer prevention and pathology and leadership of women in medicine.

Helen Marion Macpherson Mackay, F.R.C.P., London, England. First woman to be elected to the Fellowship of the Royal College of Physicians. An internationally known pediatrician.

Helen MacMurchy, C.B.E., Toronto, Canada. Worked with Sir William Osler at Johns Hopkins in fields of child welfare and public health. Chief of Division of Child Welfare, Dominion of Canada Department of Health, 1920–1934. For child welfare and public health.

Helen V. McLean. Developed Institute for Psychoanalysis in Chicago, and contributed greatly to understanding of psychiatric problems relating to pressure groups, especially Negroes. For psychiatry.

Florence R. Sabin. Had distinguished career at Johns Hopkins and Rockefeller Institute. Since so-called "retirement" conducting campaign for improvement of public health in Colorado. For medical research.

Helen B. Taussig, Associate Professor of Pediatrics, Johns Hopkins. Member of the famed Taussig-Blalock "blue baby" team of doctors. For clinical medical research.

Priscilla White, Physician, New England Deaconess Hospital and Faulkner Hospital, Boston, and instructor pediatrics, Tufts College Medical School. Has carried on extensive work in field of diabetes, giving special attention to care of diabetic children, diabetic mothers, and inheritance of diabetes. For work in diabetes.

Drs. Eliot, Hamilton, and Sabin have been active in the affairs of the A.P.H.A. Both Dr. Eliot and Dr. Hamilton have received Lasker Awards, the former in 1948, the latter in 1947. Dr. Sabin was granted honorary fellowship in 1948.

Studies of the Combined Action of Antibiotics and Sulfonamides*

C. W. PRICE, PH.D., W. A. RANDALL, PH.D., HENRY WELCH, PH.D., F.A.P.H.A., AND VELMA L. CHANDLER, PH.D.

Federal Security Agency, Food and Drug Administration, Washington, D. C.

RECENT advances in the chemotherapy of disease have proceeded along two main lines of endeavor. An intensive search is being made to discover new antibiotic agents, and numerous studies are under way to explore the possibilities of combining antibiotic agents with each other and with various sulfonamides in order to provide more effective remedies. In addition to penicillin and streptomycin, extensive clinical investigations are being conducted with polymyxin B. bacitracin, aureomycin, and chloromycetin. Anticipating that eventually some of these antibiotics may be used in combinations, and with other chemotherapeutic agents, the present study was initiated to determine what combinations might be effective. Combinations of these agents might have three possible results: the effect of the mixture may be simply additive; it may be synergistic, that is, the mixture would have a greater effect than the sum of the effects of the active ingredients; and finally, the reverse could occur and the mixture produce a lesser effect than the sum of the effects of the active constituents. The simultaneous use of more than one therapeutic agent in combating infections is designed to bring about a more rapid and effective eradication of the causative agents, to prevent the development of resistant variants, and possibly to extend the range of antibacterial activity. More than one chemotherapeutic agent might be used also in infections caused by more than one organism.

Synergistic or additive action of drug mixtures has been reported by Foley and Lee (1948) (gramicidin and penicillin); Thomas and Hayes (1947) (penicillin and sulfathiazole); Stewart (1947) (penicillin-sulfonamide); and Kolmer (1948) (penicillin-streptomycin-sulfonamides-arsenicals and bismuth compounds). The present work deals with the action of various mixtures containing penicillin, streptomycin, polymyxin, bacitracin, aureomycin, chloromycetin, sulfathiazole, sulfadiazine and sulfamerazine on *Salmonella typhosa, in vitro* and *in vivo*.

METHODS

In vitro—Dilutions of the antibiotics and the sodium salts of the sulfonamides tested were made in distilled water to the desired concentration. Two ml. quantities were placed in test tubes and 8 ml. of a broth (penassay broth, Difco) dilution of *S. typhosa* containing from 200,000 to 500,000 organisms per ml. added. The tubes were incubated at 37° C. and colony counts made at 2 hours and 5 hours.

In vivo—White mice were injected intra-abdominally with 0.6 ml. of a 6 hour culture of the same strain of *S. typhosa* used above, and immediately thereafter received by the same route

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

a single injection of the drug or drug combination under test. Twenty mice were used for each concentration of each drug or mixture, and deaths recorded at the end of 24 and 48 hours. When significant results were obtained, from 50 to 300 mice were used for retesting the effective mixture in order to obtain statistically significant data.

EXPERIMENTAL

Each individual antibiotic or sulfonamide used was first tested over a wide range of concentrations, both *in vivo* and *in vitro,* to determine its individual effects. Combinations were then prepared containing the individual drugs in a concentration which, when used singly, had a slight but definite protective or inhibitive effect. This is illustrated by an example in Table 1 for penicillin *in vitro.*

The value of 1.25 u./ml. of penicillin was selected for the *in vitro* experiments and various concentrations of the other drugs added for test purposes. The concentrations of the various drugs used in the *in vivo* experiments are given in Table 6.

In Table 2 the drug mixture and concentrations showing synergism *in vitro* are indicated by a + sign. As was expected, polymyxin and streptomycin, both highly active against Gram-negative bacteria, showed synergistic activity with the largest number of the other drugs. Penicillin fell next in line, showing a synergistic effect with three other antibiotics. Aureomycin, which is active against certain Gram-negative bacteria, showed synergism with penicillin and polymyxin. The only antibiotic which showed any synergistic effect with the sulfonamides tested was streptomycin, which was active when mixed with sulfadiazine and somewhat less so when combined with sulfathiazole. The degree of synergism observed in these experiments, using *S. typhosa* as the test organism, did not indicate any marked advantage in the use of the various effective combinations over that which was obtained by a simple increase in amount of the more active drug in the mixture.

TABLE 1

Effect of Penicillin on the Growth of S. typhosa in vitro

+ = Synergism
0 = Additive
— = Less than additive
* = 0 at 500 mcg./ml., + at 1000 mcg./ml.

In the *in vivo* studies nine drugs were utilized: penicillin, streptomycin, polymyxin, aureomycin, chloromycetin, bacitracin, sulfamerazine, sulfadiazine, and sulfathiazole. All of these drugs were tested for their protective effect in mice in several concentrations in order to ascertain that dose of drug which gave a minimal protective effect. The results obtained are given in Table 3.

From the data in this table, suitable drug concentrations were selected and then tested in combination with the other drugs listed. Certain results contained in this table should be noted. The approximate CD_{50} of the drugs tabulated are: penicillin 250 u. (150 mcg); streptomycin 3 mcg.; polymyxin 2 mcg.; aureomycin 40–50 mcg.; and chloromycetin 1,000 mcg. It was not possible to determine a CD_{50} for the sulfonamides because of their toxicity. However, since the amounts of the drugs utilized in the combined therapy were those which gave only slight but definite protection, it was not necessary to obtain a CD_{50} for the sulfonamides. In Table 4 there is given an example of the manner in which the observed combined action is expressed. A negative sign indicates an antagonistic action; a positive sign a synergistic action while the numeral simply indicates the magnitude of these effects. If the magnitude of the differences was not great the effect was considered merely additive.

TABLE 3

Protective Effect of Various Drug Concentrations on S. Typhosa Infection in Mice

Antibacterial Agent	*Amount*	*Per cent Protected*
Penicillin	10 units	0
	20 "	2
	25 "	7
	50 "	8
	100 "	9
	200 "	16
	250 "	50
	400 "	50
	500 "	77
	1,000 "	84
Streptomycin	0.5 mcg.	0
	1 "	11
	2 "	33
	3 "	52
	4 "	86
	5 "	73
	10 "	80
	50 "	100
Polymyxin	1 mcg.	8
	2 "	59
	5 "	71
	10 "	95
	20 "	100
Aureomycin	10 mcg.	13
	20 "	13
	25 "	13
	40 "	32
	50 "	65
Chloromycetin	0.1 mg.	10
	0.5 "	28
	1.0 "	47
Bacitracin — Ineffective up to toxic concentrations		
Sulfamerazine	50 mcg.	40
	125 "	30
	250 "	15
Sulfathiazole	50 mcg.	30
	100 "	0
Sulfadiazine	50 mcg.	30
	100 "	10

Thus it will be noted that 20 units of penicillin alone protected only 2 per cent of the animals while 2 mcg. of streptomycin protected 33 per cent for an expected additive protection of 35 per cent.

TABLE 4

Example Showing Method of Expressing in vivo Results

Action	*Antibacterial Agent*	*Conc.*	*Per cent Protected*	*Expected Additive Action*	*Observed Combined Action*
Antagonistic	Penicillin	20 u.	2		
	Streptomycin	2 mcg.	33		
	Combined		5	35	—30
Additive	Penicillin	100 u.	9		
	Streptomycin	10 mcg.	80		
	Combined		90	89	+ 1
Synergistic	Penicillin	200 u.	16		
	Streptomycin	2 mcg.	33		
	Combined		88	49	+39

When these two drugs were given at these concentrations simultaneously, only 5 per cent of the mice were protected. This combination of penicillin and streptomycin is therefore antagonistic and the magnitude of this antagonism is expressed by the numeral —30 obtained by subtracting the additive from the combined effects of these two drugs. In Table 5 is given the

	0.50 mg.	68	90	+22

additive effect calculated from the protection afforded by the drugs injected separately and that observed following the administration of the mixtures. The last column is simply the difference between the two.

The penicillin-streptomycin mixture showing the greatest degree of synergism was obtained by combining 200 u. of penicillin with 1 or 2 mcg. of streptomycin. This combination markedly increased the survival rate of the mice injected. The experiments using combinations of penicillin and streptomycin illustrate a point which has been frequently observed during the course of this work, namely, that in order to demonstrate a significant synergistic effect it is necessary to employ proper concentrations of the drugs. Significant synergism can only be demonstrated within certain narrow limits of drug concentrations. The combinations of penicillin and aureomycin utilized did not show any significant synergism. Penicillin and sulfadiazine produced a synergistic effect when 200 u. of penicillin and 50 mcg. of sulfadiazine were combined. Penicillin and polymyxin showed a marked antagonistic action especially when utilized in concentrations of 200 u. and 2 mcg. respectively. Assays showed that no destruction of either drug occurred before the mixture was injected. This marked antagonism also occurred with other drug-polymyxin mixtures which are not recorded in the table. Streptomycin-aureomycin combinations in the doses utilized produced only what were considered additive effects. Streptomycin and sulfadiazine showed synergism at all concentrations tested. Sulfathiazole and sulfamerazine produced a synergistic effect when combined with penicillin, streptomycin, or chloromycetin, while only an additive effect was obtained with the other antibiotics tested in combination with these sulfonamides.

It is apparent by inspection of Tables 2 and 5 that certain drug combinations often give different results when tested by the two methods used. Thus, both penicillin and chloromycetin combined with two sulfonamides tested by the mouse protection method showed synergism, while the *in vitro* test failed to demonstrate anything more than an additive action. Similarly, mixtures of penicillin and polymyxin, or streptomycin and polymyxin, show antagonism only when tested *in vivo,* while a synergistic effect was demonstrated *in vitro.* The results obtained with the various chemotherapeutic mixtures utilizing *S. typhosa* as a test organism *in vitro* and *in vivo* illustrate the difficulties involved in attempting to utilize an *in vitro* method as a sole basis for clinical trial.

SUMMARY

1. Combinations of aureomycin, bacitracin, chloromycetin, penicillin, polymxin, streptomycin, sulfadiazine, sulfamerazine, and sulfathiazole were tested for possible synergistic action utilizing *S. typhosa* as a test organism, *in vitro* and *in vivo.*

2. Of the combinations tested *in vitro,* polymyxin showed a synergistic effect with aureomycin, bacitracin, penicillin, and streptomycin; penicillin with aureomycin and streptomycin; and streptomycin with sulfadiazine and sulfathiazole.

3. Of the combinations tested *in vivo,* penicillin produced a synergistic effect with streptomycin, sulfadiazine, aureomycin, sulfamerazine, and sulfathiazole; streptomycin with sulfadiazine, sulfamerazine, and sulfathiazole; and chloromycetin with sulfamerazine and sulfathiazole.

4. Although a synergistic action was demonstrable with a number of combinations of the chemotherapeutic agents tested, in only 50 per cent of these combinations did the *in vitro* method correlate with *in vivo* tests.

Importance of Antigenic Composition of Influenza Virus Vaccine in Protecting against the Natural Disease*†

Observations during the Winter of 1947–1948

JONAS E. SALK, M.D., AND PHILIP C. SURIANO, CAPT., M.C.

The Virus Research Laboratory, Department of Bacteriology, School of Medicine, University of Pittsburgh; and the Dispensary Service, 1262nd Area Service Unit, Fort Dix, New Jersey

AS is now well known, convincing evidence was gathered in 1943–1944,[1–3] and again in 1945–1946 [4, 5] indicating that susceptibility to epidemic influenza could be modified by subcutaneous vaccination. The procedure found to be effective on those two occasions was repeated again in the winter of 1946–1947.[6] This time, however, it was without demonstrable effect.

The failure of vaccination to influence susceptibility in the spring of 1947 was readily explained by the finding that the virus then in circulation was significantly different antigenically from the virus-antigens included in the vaccine.[6–11] It is of special interest, too, that the 1947 virus, although similar to a strain isolated in Australia in the fall of 1946,[12] differed from others that had been isolated in previous outbreaks.

These experiences emphasized the desirability of continuing the field studies of vaccination against influenza for evaluation in future epidemics. The matter was discussed at a meeting of a committee of the Army Epidemiological Board and of representatives of the Office of the Surgeon General of the Army. The members of the committee were Dr. Colin M. MacLeod, Dr. Thomas Francis, Jr., Dr. John H. Dingle, Dr. Joseph E. Smadel, and Dr. Jonas E. Salk. The representatives of the Office of the Surgeon General were Col. Tom F. Whayne, Lt. Col. Frank L. Bauer, and Lt. Col. Arthur Long. At this meeting, plans were inaugurated for carrying out field studies in the Army, under the auspices of the Commission on Influenza. The observations reported here comprise the results of the first year's effort in a program that will be continued over a number of years, and until the required information is obtained.

PLAN OF THE STUDY

It is desired to explain the limiting circumstances that prevailed at the time of planning the 1947–1948 study. Before this particular investigation was contemplated the policy of the Army had already been adopted to vaccinate

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

† This investigation was conducted under the auspices of the Commission on Influenza, Army Epidemiological Board, United States Army, Office of the Surgeon General, Washington, D. C.

all troops in the fall or early winter of that year. A new supply of vaccine was ordered and it was to contain the strain of virus that had by-passed the vaccine used in the preceding winter and spring. Because the quantity of new-formula material that could be promised for delivery in the fall was insufficient to supply the entire Army, it had been decided to supplement this limited amount with old-formula material to be used in certain specified areas.

Under the circumstances then prevailing the inclusion of an *unvaccinated* control group could not be considered in any trials that were to be carried out in the Army. The only kind of a study that could be conducted was one in which a comparison would be made between groups given the *two different* vaccines. The two vaccine preparations were the same in so far as both contained the Type A and Type B components, but they differed in respect to the presence or absence of the new component that is now referred to as Type A-prime.

It is obvious that a study of this sort would yield information on the efficacy of vaccination only if the virus operating during the period in question were similar to the one present in the new vaccine and absent from the other. Although this plan was far from ideal, it did serve the purpose of initiating the field trials in the Army without further delay and offered the opportunity to gain experience that would be of value the following year.

PROCEDURE

Accordingly, arrangements were made for a study to be conducted at Fort Dix, New Jersey. Approximately 60 per cent of the strength of this induction and training center of 15,000 were trainees who remained for approximately 13 weeks; the remainder were cadre and personnel of the post detachments.

The scheme for distributing the two vaccines equally in the population was to give the *old-formula* material to men with serial numbers ending in *odd* digits and the *new material* to men with numbers ending in *even* digits. On November 14, 1947, all of the trainees and cadre of the training companies were inoculated according to this scheme, and in the following week the detachments were similarly treated. Subsequently, the same plan was employed in the treatment of all newly formed companies. Influenza vaccine was administered along with the other immunizations at the time of medical processing, thereby maintaining the division of the entire post into two groups. Great care was exercised to maintain the distribution of the vaccines according to the serial-number scheme and to reduce exceptions and error to a minimum. This procedure was continued until April 1, 1948.

The two vaccines used in this study were prepared commercially. The *old-formula material* was from a single batch of vaccine prepared for use in the winter of 1945–1946.[4] The virus in this vaccine was concentrated by the method of red cell adsorption-elution.[13] At the time of use in this study the vaccine was more than two years old; and this was about one year beyond the expiration date. The strains of virus in this vaccine were PR8 and Weiss, Type A, and Lee, Type B. The *new-formula material* was from a single batch, freshly prepared just a few months prior to use in this study. Concentration of virus was affected by Sharples centrifugation,[14, 15] and the strains represented were PR8 (Type A), FM1 (Type A-prime) and Lee (Type B).

Even though the two vaccines differed in strain composition it was still necessary to evaluate serologically the effect of each in terms of their different antigenic components. This was done by comparing antibody titers in serum collected before and again two weeks

TABLE 1

Geometric Mean Antibody Titers Before and Two Weeks After Vaccination in Subjects Inoculated with "Old-Formula" and "New-Formula" Influenza Virus Vaccine*

Antigen in Serological Test	"Old-Formula" Vaccine (142 Subjects)			"New-Formula" Vaccine (81 Subjects)		
	Pre-Vacc.	Post-Vacc.	-Fold Change	Pre-Vacc.	Post-Vacc.	-Fold Change
PR8	70	536	7.7	65	440	6.8
LEE	80	880	11.0	75	640	8.5
FM1	68	163	2.4	73	438	6.0

"Old-Formula Vaccine" was from the supply prepared for use in the winter of 1945–1946 and had an expiration date of December, 1946. It was administered to these subjects on November 14, 1947. This vaccine contained the PR8 and Weiss Strains of Type A and the Lee Strain of Type B virus.

"New-Formula Vaccine" was freshly prepared just a few months prior to use in November, 1947. It contained the PR8 and FM1 strains of Type A and the Lee strain of Type B virus.

* Antibody titers (agglutination-inhibition) are expressed in terms of the dilution of serum inhibiting 4 units of hemagglutinin.

after inoculation. The data, for groups of individuals given the different vaccines, are summarized in Table 1 in terms of the geometric mean titer as well as the -fold increase as measured with three different antigens. Although the *old-formula vaccine* induced a distinct elevation in antibody level for the PR8 and Lee antigens, there was only a slight increase in antibody for the FM1 antigen. The *new vaccine* was distinctly more effective than the *old* in terms of the antibody response measured with the FM1 antigen. It is interesting to note that the older preparation, although one year beyond its expiration date, appears to have induced a somewhat better response than the new material to the PR8 and Lee components.

The antigenicity of the two vaccines was also tested in mice and they were found to be equally effective with respect to the PR8 (Type A) and Lee (Type B) components. As was to be expected the *old-formula vaccine* failed to induce the formation of any antibody for the FM1 strain (Type A-prime), while the new material was as effective in the formation of antibody for FM1 as it was for the PR8 and Lee strains.

OBSERVATIONS

In planning the clinical and epidemiological aspects of the study it had been decided to base any evaluation of vaccination effect upon the number of cases of respiratory disease hospitalized or put on quarters. Although the limitation of this procedure is thoroughly appreciated it was believed to be sufficiently reliable to evaluate the crude data obtained in this manner, particularly since the groups were to be equal in size and were to be treated in the same way. Moreover, an adequate sampling of cases for serological study was to be made.

After the study was begun careful records were kept of all admissions to hospital or to quarters for reasons of respiratory disease. In addition, records were kept of the number of admissions to hospital from the odd and even serial-numbered groups for other illnesses as well.

Before presenting the data it is desired to point out that proven cases of influenza among patients in Army hospitals have usually been found among those diagnosed as "nasopharyngitis," or occasionally as "laryngitis" or "bronchitis." Even though the systemic component of the illness may predominate and may strongly suggest the diagnosis of influenza, this diagnosis is not used and preference is given to the terms referring to the area of the

TABLE 2

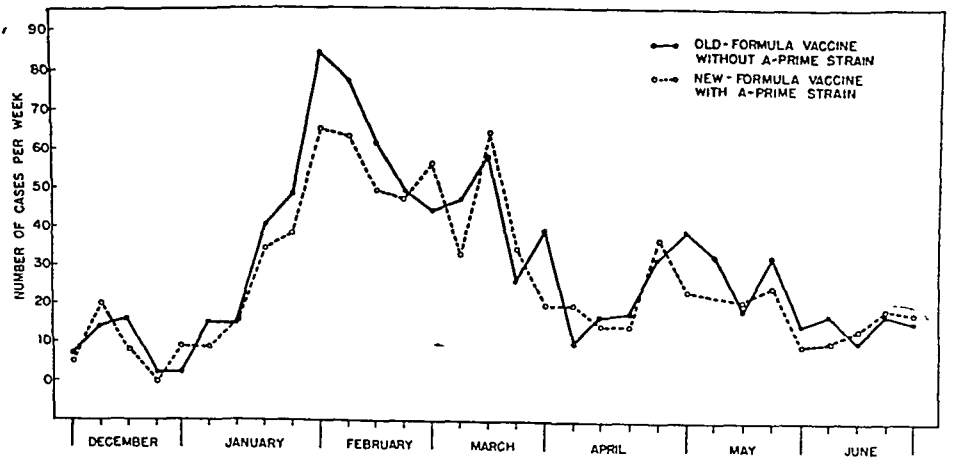
Comparison of Weekly Incidence of Nasopharyngitis, Laryngitis and Bronchitis in Two Groups Given Old-formula and New-formula Influenza Virus Vaccine

FORT DIX, N J, 1947-48



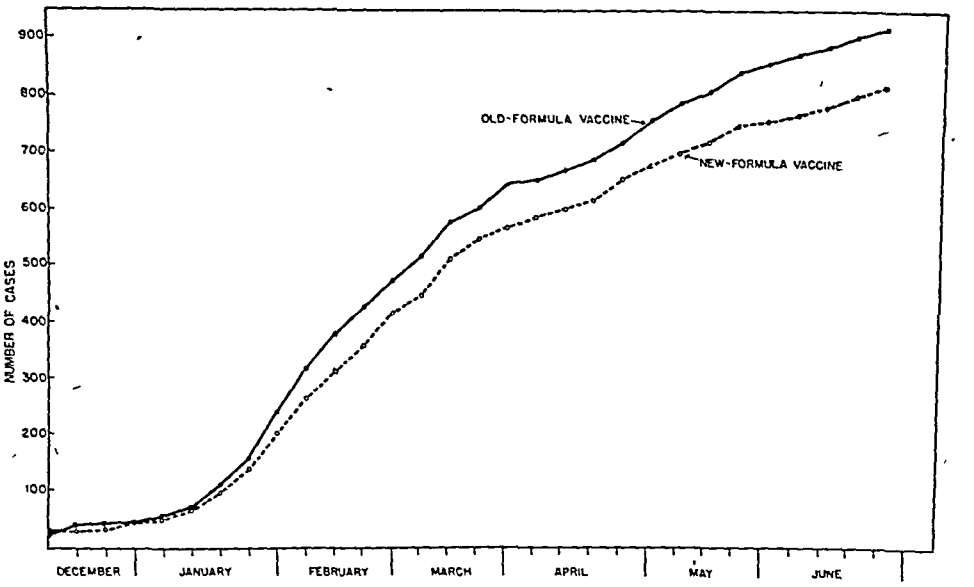


FIGURE 2

Comparison of Cumulative Number of Cases of Nasopharyngitis, Laryngitis and Bronchitis in Two Groups Given Old-formula and New-formula Influenza Virus Vaccine

1 DEC., 1947 THROUGH 1 JULY, 1948

respiratory tract most prominently involved. It is for this reason that special attention was given to the group of cases diagnosed as nasopharyngitis, laryngitis, and bronchitis.

The data in Table 2 and Figure 1 indicate the number of patients hospitalized or put on quarters each week with such diagnoses. In almost all cases the presence of a temperature of 100° or higher was the basis for inclusion in these categories. It will be seen that in both odd and even serial-numbered groups, which had been given the "old"- and "new"-formula vaccines, respectively, there was a distinct increase in the incidence of respiratory disease beginning in mid-January and lasting until mid-March. Then, at the end of April and lasting a few weeks into May, there was a second noticeable increase.

It is difficult to see from Figure 1 that, during the period when the amount of respiratory disease was increased, the number of illnesses in the odd half of the population was somewhat in excess of that in the even half. This trend is shown more clearly when the data are presented cumulatively.

Figure 2 shows graphically (also see Table 2) the cumulative number of cases in the odd and even groups from December, 1947, to July, 1948. It is clear that the number of cases from the odd group exceeded the number of cases from the even group. The extent of the difference at the end of the observation period was 101 cases.

The question at once arises as to the significance of this difference. The data in the next few figures and tables are intended to help answer this question.

Figure 3 contains a graph of the cumulative number of admissions to hospital for a variety of conditions other than nasopharyngitis. The data for the months December, 1947, through April, 1948, include hospital admissions for injuries, surgery, venereal diseases, and neuropsychiatric conditions; and to these have been added admissions for tonsillitis, scarlet fever, pneumonia, otitis media, and mumps. The data for

the first group were kept only until the end of April, 1948, since the original intention was to conclude the study period as of the latter date. However, the graph was extended by charting the additional admissions for the infectious diseases mentioned, over the remainder of the period, because the nasopharyngitis group was carried to the end of June. The reason for the extension will be evident from the data in Figure 3.

Figure 3 shows that through the period of observation there was no difference in the cumulative admissions from the odd and even groups, in terms of the diagnoses noted above. In the majority of instances the respective points for any one week fall so close together as to be indistinguishable. The two inseparable lines describing the cumulative number of cases of "*other*" diseases are in contrast to the two distinctly divergent lines for *nasopharyngitis, etc.*, as shown in Figure 2.

Although the data in Figure 2 clearly indicate that a greater number of cases of respiratory disease had occurred in that half of the population with odd serial numbers, it is not easy to tell from the graph when this difference occurred or to what extent. In order to show this difference, a series of points was plotted (Figure 4) to demonstrate the extent to which the cumulative number of admissions from the odd group exceeded admissions from the even group at the end of each weekly period from December, 1947, to July, 1948.

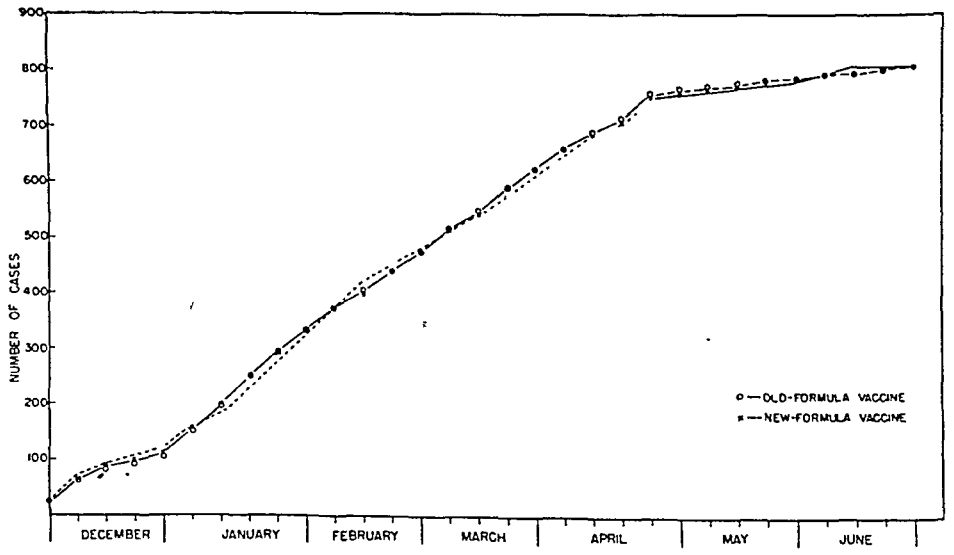
Figure 4 shows a comparison of the curve expressing the degree of difference in the cumulative admissions from the odd and even groups for common respiratory disease (which would also include the influenzas) and for other diseases. It is readily seen that illnesses *other* than nasopharyngitis occurred in equal numbers of odd and even men throughout the observation period. This is indicated by the fluctuation of the difference curve near the zero-line.

Cases of common respiratory disease also occurred in equal numbers in odd and even groups during December, 1947, and early January, 1948. However, beginning in mid-January the number of cases among *odd* men began

FIGURE 3

Comparison of Cumulative Number of Cases of Illness other than Common Respiratory Disease in Two Groups Given Old-formula and New-formula Influenza Virus Vaccine

1 DEC., 1947 THROUGH 1 JULY, 1948



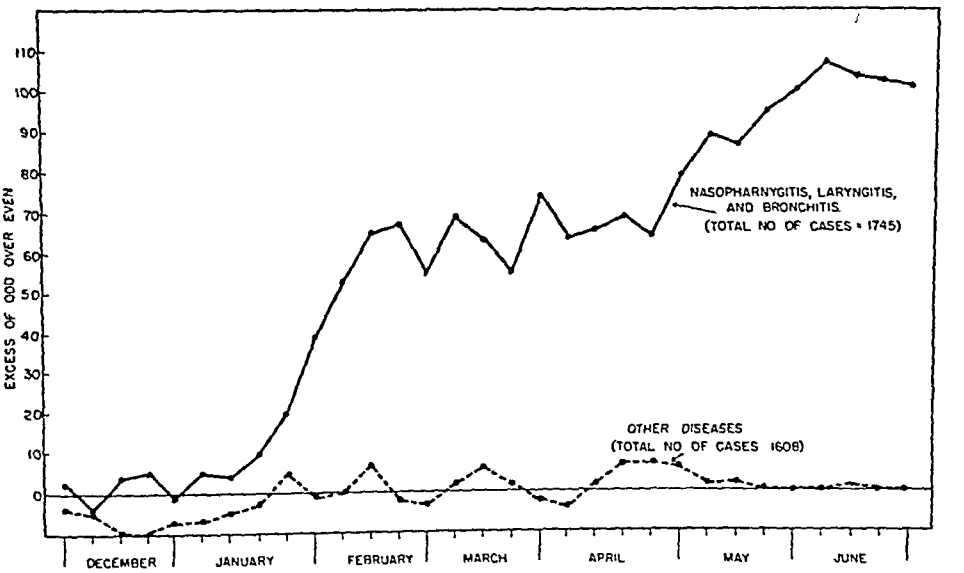


FIGURE 4

Difference in Cumulative Number of Cases of Illness in Odd- and Even-Numbered Men Given Old formula and New-formula Influenza Virus Vaccine, Respectively

to exceed the number of cases from the *even* group. This continued until the end of February. Although, as shown in Figure 1, the high incidence of respiratory disease was maintained until the end of March, before declining to lower levels, the number of such cases among odd and even men was essentially the same through March and April. Then, during the second increase in common respiratory disease in April and May, there occurred another period when odd-numbered cases exceeded even-numbered ones. In June both groups were again equally represented.

It appears from these data that some factor was operative during the periods in January-February and April-May when the even-numbered group was favored with fewer cases of respiratory disease. It is to be recalled that the odd- and even-numbered groups differed with respect to one factor only; the even-numbered men had received the "new" vaccine containing antigens of the A-prime strain as well as the A and B strains, while the odd-numbered men had received so-called "old" vaccine that contained only the A and B antigens, but not the A-prime antigen.

It seems reasonable to conclude that the occurrence of 101 fewer cases of respiratory disease in that half of the population with even serial numbers was related to the treatment given. The data shown in the foregoing charts are summarized in Table 3.

For comparison with the numbers of odd and even men diagnosed as having had *nasopharyngitis, laryngitis,* and *bronchitis,* there is shown the number of cases of *other illnesses* from the odd and even groups. In addition the number of odd and even men in eight companies selected at random is tabulated for comparison. This number was selected to show how many odd and even men are found in a randomly selected group comparable in size to those in the illness categories.

It is clear that the difference of 101 cases of nasopharyngitis, etc., between the odd and even groups is significant in view of the fact that little or no difference between odd and even is evident in other categories of similar size. Al-

TABLE 3

Comparison of the Total Number of Cases of Common Respiratory Disease, and of Other Diseases, in Odd and Even Groups Occurring in the Interval December 1, 1947–July 2, 1948

	Number of Cases			Difference
	Total	Odd *	Even *	Odd-Even
Nasopharyngitis, etc.[1]	1,745	923	822	+101
Other Diseases [2]	1,608	804	804	0
Population Control [3]	1,691	848	843	+5

* The odd group received old-formula vaccine and the even group received new-formula vaccine.

[1] Includes cases hospitalized or put on quarters for illnesses diagnosed as nasopharyngitis, laryngitis, or bronchitis.

[2] Includes admissions to hospital for venereal disease, surgery, injuries, neuropsychiatric conditions as well as the pneumonias, tonsillitis, scarlet fever, otitis media, and mumps.

[3] Represents the number of men with odd and even serial numbers in eight companies selected at random.

TABLE 4

Tabulation of Number of Cases of Nasopharyngitis, etc., Among Men with Odd and Even Serial Numbers in 5 Successive Intervals Between December 1, 1947, and July 2, 1948

Inclusive Dates	Length in Weeks	Odd	Even	Excess of Odd over Even
Dec. 1–Jan. 15	6	56	51	+ 5
Jan. 16–Feb. 26	6	325	265	+60
Feb. 27–April 30	10	340	341	— 1
May 1–June 17	6	157	114	+ 43
June 18–July 2	3	45	51	— 6
Total	31	923	822	+101

though a statistical test for significance supports this statement, the data shown in Tables 4 and 5 are presented to strengthen the opinion that the divergence is probably due to a difference in the number of cases of influenza in the two groups and that this was brought about as a result of vaccination.

In Table 4 it is seen that the difference between odd and even, with respect to numbers of cases of nasopharyngitis, occurred in two distinct periods. From the serological data (to be presented below) it is evident that a flurry of influenza occurred during the first of these periods (January 16–February 26), and it may be presumed to have occurred in recognizable numbers during the second period (May 1–June 17).

Table 5 contains a comparison of the numbers of cases of nasopharyngitis in odd and even groups during the period of presumed virus activity and in the remainder of the observation period.

TABLE 5

Numbers of Cases of Nasopharyngitis, etc., from Odd and Even Groups in the Intervals of Presumed Influenza Virus Activity as Compared with the Remainder of the Observation Period

Periods of Presumed Virus Activity	Length in Weeks	Odd	Even	Excess of Odd over Even
Jan. 16–Feb. 26 May 1–June 17	12	482	379	+103
Remaining Periods				
Dec. 1–Jan. 15 Feb. 27–April 30 June 16–July 2	19	441	443	— 2
Total	31	923	822	+101

Although comparable numbers of cases occurred during both periods the difference between odd and even was evident only during the intervals January 16–February 26 and May 1–June 17.

SEROLOGICAL STUDIES

At the time the difference between the odd and even groups was recognized, serological tests had not yet been done on the acute and convalescent sera collected from patients hospitalized with respiratory disease. Paired specimens were collected from more than 500 individuals who were ill in the period of the highest incidence of illness. In view of the analysis shown in the foregoing, it was not surprising to find that a certain number of cases of influenza A had occurred; nor was it surprising that the strain of virus prevalent appeared to be, from the serological findings, more closely related to the 1947 virus (Type A-prime).

Of the group of 528 paired serum samples only 28, or about 5 per cent, were found to have significant antibody increases (4-fold or more) in the convalescent sera when tested with the FM1 strain (Type A-prime). Of the 28, only 4 were detected to have a 4-fold rise in titer when tested with the PR8 strain (Type A), and 9 more showed a 2-fold change in titer; thus suggesting a closer antigenic relationship to the A-prime subgroup of influenza virus Type A. It is interesting to note that 19 of the 28 positive cases were individuals with odd serial numbers, and 9 were from the even-numbered group.

The relatively small number of serologically positive cases indicates that only a small proportion of the illnesses responsible for the peak in February and March was due to the influenza virus. The cases examined serologically were those occurring in that period; blood for study was not obtained during the flurry in the late spring. The small number of cases of proven influenza were not concentrated in any particular organizations.

DISCUSSION

The serological data are of help in evaluating the clinical and epidemiological findings. The fact that the proportion of serologically proven cases of influenza was so low makes the difference of 100 cases between the odd and even groups more significant than if the proportion of influenza infections was high. It is not possible to estimate the per cent reduction in the influenza attack rate resulting from vaccination without resorting to too many assumptions in arriving at an estimate of the number of cases of illness attributable to the influenza virus. The result would be of questionable value. Suffice it to say that when two vaccinated groups of equal size in the same population were compared, the one given the vaccine that furnished the broader antigenic coverage experienced approximately 100 fewer cases of respiratory disease as compared to a similar group given a vaccine that was defective with respect to the particular antigen for the prevalent virus.

Largely because of the nature of the "control" group and the low incidence of cases of proven influenza, it is not desired to draw far-reaching conclusions from this study. Nevertheless, several things have been learned.

1. As an addition to information from earlier studies, which indicated that vaccination reduces susceptibility to naturally occurring influenza A and B, the present investigations show that susceptibility to the disease caused by a virus of the A-prime sub-group can also be reduced by vaccination. The failure of vaccination to influence susceptibility in the spring of 1947, together with the findings in the present study, emphasize the necessity for continuing to include the new antigen in

vaccines of the future, and emphasize a problem long recognized, namely the necessity for further study to determine the most effective antigenic formula.

2. From independent studies of the Fort Dix epidemiological data by Dr. Philip Sartwell, of the School of Hygiene of Johns Hopkins University, as well as the observations that have been described, it seems that influenza *did not* occur in epidemic proportions at Fort Dix during the period of this study. Accordingly, it might be concluded that a proportion, at least, of influenza virus infections that occur *sporadically* or *endemically* can be prevented by vaccination.

Even though influenza vaccines may not yet be complete in their coverage they do contain, nevertheless, antigenic components for certain viruses that are potentially the cause of moderately severe disease in man that may be extensively disseminated, sporadically or epidemically.

In closing, a word of optimism is in order to counteract opinions that have emanated from various quarters of disappointment in the "failure" of vaccination to influence susceptibility to influenza in the spring of 1947. In the opinion of others, the so-called failure has been regarded as a finding of great importance. One cannot escape the fact that at that time an etiologic agent was discovered capable of causing widespread disease in man, and by virtue of the vaccination studies, its antigenic difference from previously isolated strains of influenza virus Type A was clearly recognized. Some have stated that this strain is a "mutation" and that this might mean that we will always be immunizing against a disease that occurred the year before.

There seems to be something wrong with this idea from a biological viewpoint. It might be questioned whether the new strain may not have prevailed at some previous time. It is entirely possible that it may have escaped detection in recent years, or that it had been more active prior to the time when the influenza viruses were so easily isolated.

It is a more hopeful view to consider that there is a finite number of antigenic varieties, or sub-groups, and that we may not yet have them all in the various laboratories throughout the world, nor is the classification yet complete.

The results of the work of the strain study center of the Influenza Commission and the results of the field studies, already under way for 1948–1949 and to be continued indefinitely into the future, should provide the answers.

SUMMARY

1. In the winter of 1947–1948 studies on vaccination against influenza were carried out in a military installation. Due to limiting circumstances that are described, the study involved a comparison of two vaccines that differed in strain composition. Representative strains of Type A and Type B viruses were present in both. However, only one of the two vaccines contained, in addition, the antigenic variant of the Type A strain (referred to as A-prime) that was prevalent during the winter and spring of 1946–1947.

2. The entire population was vaccinated; men with odd serial numbers received one of the vaccines and the even-numbered men received the other. Records were kept of admissions to hospitals and to quarters for all diseases. The data revealed that the group given the new-formula vaccine, which contained the A-prime antigen, experienced approximately 100 fewer cases of respiratory disease. As for other illnesses there was no difference, in this respect, between groups given the different vaccines.

3. Serological tests of acute and convalescent sera revealed the occurrence of a small proportion of cases of influenza virus infections during the period of increased prevalence of respiratory disease. Moreover, from the serological studies it appears that the prevalent virus was related to the A-prime sub-group, which was represented in only one of the two vaccines.

4. These observations indicate that during a period in which *influenza occurred sporadically or endemically,* the use of a vaccine hav-

ing the specific as well as the broader antigenic coverage, was effective in reducing the number of cases of respiratory disease.

5. The significance of the existence of antigenic varieties of influenza virus strains is discussed in relation to the problem of immunization.

ACKNOWLEDGMENTS: These studies could not have been undertaken without the interest and willing coöperation of certain key persons in the organizations involved. It is a pleasure to express our grateful appreciation to Lt. Col. Frank W. Threadgill, Post Surgeon at Fort Dix; to Col. Charles W. Farinacci, Commanding Officer of the First Army Area Medical Laboratory; and to Col. Leroy D. Soper, Commanding Officer of Tilton General Hospital. It is desired to acknowledge, too, the generous assistance of the staffs of the respective organizations.

As noted in the text, these studies were initiated following the advice of a committee of the Army Epidemiological Board and of members of the Office of the Surgeon General. The advice and suggestions of the committee in planning the work are greatly appreciated. It is desired to acknowledge particularly the helpfulness of Col. Tom F. Whayne, Lt. Col. Frank L. Bauer, and Maj. Thomas G. Faison. The continued interest and advice of Dr. Thomas Francis, Jr., is warmly appreciated.

Mental Hygiene Statistics

The Division of Mental Hygiene of the U. S. Public Health Service on November 1, 1948, published the first of a series of current reports on Mental Hygiene Statistics to be designated as the MH-S series, and making available the results of the annual Survey of Patients in Mental Institutions earlier than the final published report. The first report shows by states and regional division normal capacity, percentage of overcrowding, the full-time administrative staffs, and expenditures for the maintenance of state hospitals for mental disease in 1946. The Annual Census of Patients in Mental Institutions was transferred from the Census Bureau to the Public Health Service early in 1948.

A Public Health Rh Program on a State-wide Scale*

CLIFFORD I. ARGALL

Chief, Rh and Blood Grouping Section, Division of Laboratories, State Department of Health, Salt Lake City, Utah

THE philosophy of any state as to what constitutes public health work will determine its attitude toward an Rh program. The widening concept of the function of a public health laboratory has made it possible to include blood grouping as one of the essential procedures in many states. Evidence that many neonatal deaths could be prevented by giving the attending physician advance warning of possible trouble prompted the Utah State Board of Health to approve an Rh typing program without qualification.

The drafting of a set of comprehensive plans was made a joint responsibility of the Division of Laboratories and the Division of Maternal and Child Health; the former to provide equipment and secure personnel, and the latter to pay the cost of all salaries and biologicals. These plans were completed early in 1946, but until a dependable supply of antiserum and additional personnel were assured, the program was delayed until July, 1947. The final draft contained three major objectives:

1. Insuring the Rh typing of every pregnant woman
2. Finding new sources of typing sera
3. Aiding communities to establish blood donor lists

All three objectives have been thoroughly covered. Every blood sample labelled "prenatal" is routinely checked for A-B-O and Rh types. During the first year, over 96 per cent of all gravid women in Utah were typed by the State Health Laboratory, indicating that the program was well accepted by the physicians.

Due to the lack of personnel, no attempt has been made to process typing sera for our own use. The Blood Grouping Laboratory of the University of Utah is engaged in preparing such sera, and many of our reagents are secured from that source. By making available to Dr. G. Albin Matson,† head of the University Laboratory, lists of the women whom we find to be sensitized, we are assuring ourselves and other laboratories a much larger supply of serum.

The Utah Health Department does not have facilities to put into effect a state blood bank such as that of Massachusetts.[1] As a substitute, we are permitting physicians to collect blood from volunteers for typing, and it is up to the physician to obtain donors when needed. This phase of the program was ignored until we could be sure of an ample supply of anti-C and anti-E sera. The reason lies in the fact that cross-matches as done in many hospital laboratories do not take into account the possibility of Rh antibodies in the recipient. To avoid the least chance

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

† Now Director of Blood Banks, Latter Day Saints Hospital System.

of transfusion reaction, it is necessary that any donor reported "negative" lack all three antigens.

In fulfilling the basic points in the Rh program, we found the answers to several questions which had been raised when the plans were first outlined. Chief among these were cost, personnel, space and equipment, reliability of mailed samples, and scope of the program.

Cost—The total cost to Utah for the first year was slightly over $10,000 and estimates for the present year indicate that the amount spent will be approximately $11,000 for a greatly enlarged program. Table 1 gives a breakdown of these figures.

Personnel—The present personnel consisting of a specialized serologist as Chief of Section, a laboratory helper, and a secretary, is just adequate to handle the number of typings and titrations with the methods now in use.

Space and Equipment—Lack of space is frequently mentioned as a reason for not doing Rh work. Our entire Rh section is compressed into an area of 91 sq. ft. This is too little, to be sure, but the work gets done. With the exception of a view box for slide testing, the essential equipment such as centrifuges, refrigerator, water bath, etc., should be found in any laboratory. While a deep freeze unit is desirable for storing serum it is not necessary.

Reliability of Mailed Samples—In 1947, the New Jersey Laboratory sent out a questionnaire including the query "Are mailed samples reliable for typing?" The laboratories doing Rh work at that time agreed that such samples are suitable, but cited no satisfactory experimental evidence. Controlled work on our part, still in progress, has been advanced to a point that has satisfied us that even badly hemolyzed specimens can be typed with complete certainty.

Scope—Prenatal specimens are typed routinely; husbands (or families) of Rh-negative prenatals and blood donors

TABLE 1

Cost of Rh Program in Utah for 1947, Estimated for 1948

	1948	—	—	—	$0.114	—

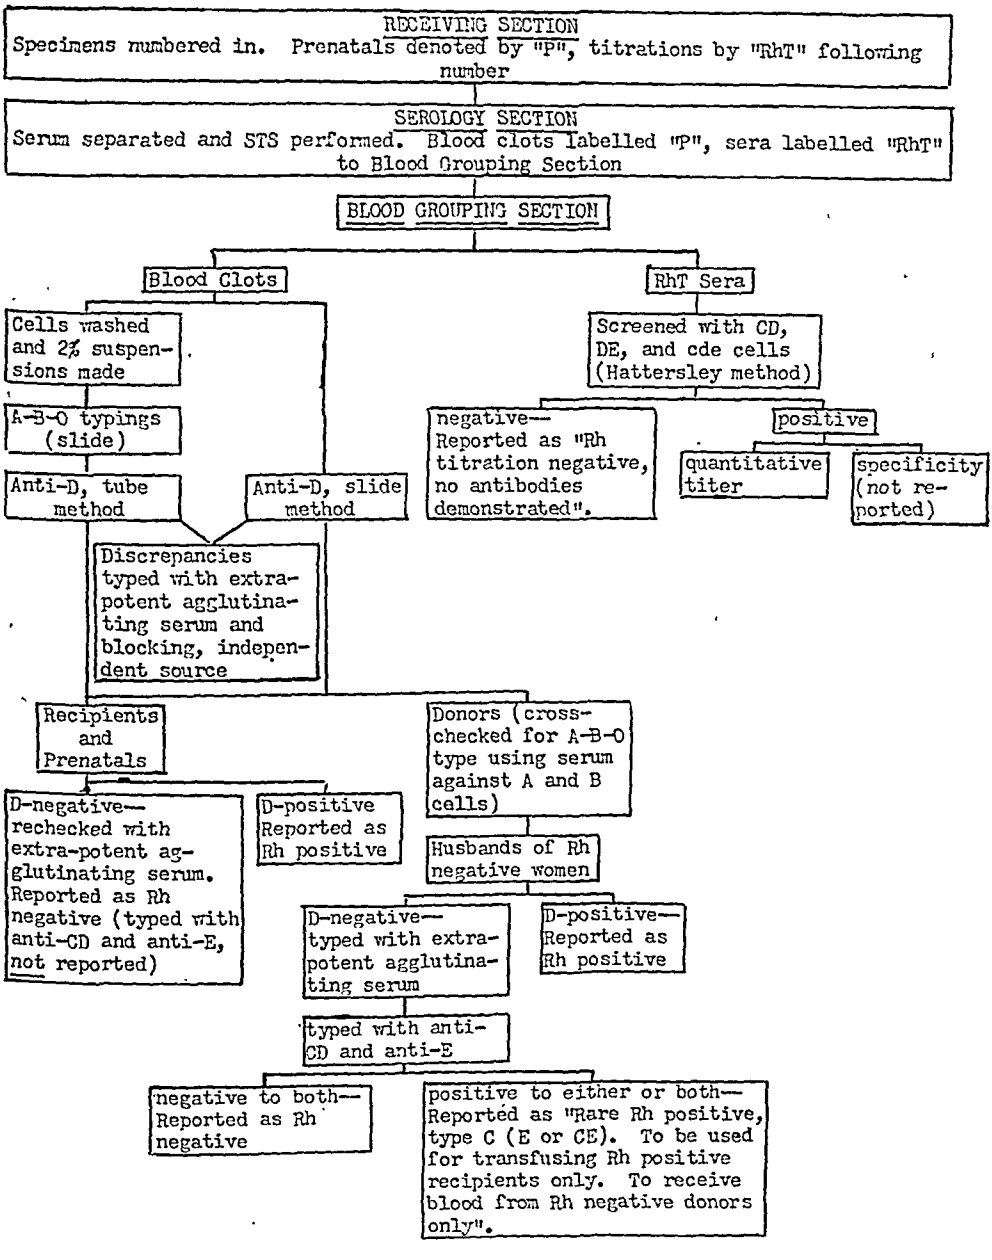
upon request. Premarital typings are refused, for tripling the size and cost of our present organization to satisfy curiosity does not seem justifiable. As pointed out by Cappell,[2] specimens from gravid women should be typed with anti-D serum only, and a highly effective program may be based on the use of the one serum. We subtype all D-negatives with anti-CD and anti-E sera, but for the prenatals report the result of the D typings only. These subtypings represent our only method for obtaining a steady supply of C and E cells to use in specificity tests. In some instances, they have enabled us to explain to the physician apparently discrepant results between our typings and those of laboratories using anti-CD serum for all purposes. Hr typing with anti-c serum is limited to husbands of known sensitized women. Because of the great element of uncertainty in these tests we recommend familial studies as well. A very guarded interpretation is sent with each report.

With regard to tests for sensitization, we feel that these should be an integral part of the routine in any public health laboratory doing Rh work. Public health emphasis is on prevention, and the only method for early recognition and treatment of erythroblastosis is by testing the mother's serum before delivery. Performing titrations on only those cases showing a suggestive clinical history or for the purpose of confirming a diagnosis is not sufficient to accomplish the aims of a public health service. Upon request we are trying routine tests for antibody on all D-negative prenatals, using the serum from the same specimen with which they were typed. A brief experience has shown that these extra tests can be done without increasing our personnel, and with very little extra cost. However, many women first see their doctor in the early months of pregnancy and antibodies are frequently not demonstrable until later. It has been our experience that many physicians are content with a single negative titration report, making the value of routine antibody determinations questionable, especially at an early stage.

Figure 1 gives an outline of the procedures in use. We have tried every type of test we could, including evaluation of some not mentioned here, retaining those found to be best adapted for large-scale work in our hands.

Use of an exceptionally potent agglutinating serum as well as a blocking serum from an independent source is necessary to check anomalous results between the tube and slide tests. We have found a few specimens which typed consistently positive by one method and negative by the other.

The tube test has been well standardized, and no departures have been made from the usual methods.



The slide test using clotted blood is readily adaptable to large-scale work. One person is able to run an average day's 85 specimens in 40 minutes.

It may be of interest to mention that the antibody in four samples would have been missed if the Hattersley technique[3] were not employed. Three showed a marked prozone in the blocking titration, while the fourth gave no reaction whatever unless centrifuged before incubation. Specificity tests are made against type "O" cells of Rh groups CD, DE, C, E, and Rh-negative. Several of each type are used; 8.5 per cent of the women tested are sensitized.

When the program began, the tube test with agglutinating serum was the only one used. During the time that this method was being followed the accuracy of our typings was only 99.2 per cent. Since the adoption of the multiple-check system, the accuracy has jumped to 99.91 per cent. These figures are based on repeated samples on the same individuals.

The fact that Utah has a prenatal STS law and that we do the vast ma-

Figure 1
FLOW SHEET OF PROCEDURES

jority of such specimens puts us in the best position to act as a central Rh laboratory for the entire state. van Saun [4] has emphasized this value of centralization, basing her arguments on the inadequacy of hospitals for the work, and the control on typing sera offered by doing large numbers of samples. Despite the improvement in typing sera brought about by the NIH standards, a careful check is still necessary. For example, we have received one lot of anti-D serum from a licensed firm which agglutinated only 40 out of

TABLE 2

Record of Results of Rh Program

Total specimens received	26,163

Total typings	25,787	
Individuals typed	23,661	
D-positive	19,647	83.04%
D-negative	4,014	16.96%
Screening test for antibodies	2,001	
Individuals tested	1,106	
Positive	94	8.50%
Total births in Utah	21,015	
Prenatal typings — same period	20,335	96.70%

200 known D-positive samples. In another instance, the alpha agglutinin was incompletely absorbed, while still another lot, labelled anti-D, contained anti-C antibody as well.

There are other reasons why a central laboratory is better for Rh typing than a number of small ones. The gathering of unselected statistical data and the dissemination of information from the literature can well be done in such a unit. Concentration of the comparatively few Rh specialists is desirable until more and better trained personnel become available. By better trained, we mean not only in the techniques of Rh typing, but in knowing what sera to use and when to use them. Misuse of typing serum has come to our attention on several occasions. A central laboratory can act as a focal point for those laboratories desiring to check their results against others. One step in this direction is an evaluation study on a voluntary basis which will cover about 50 per cent of the laboratories of Utah. This will be an annual service. As soon as enough public health laboratories begin Rh typing, a national evaluation similar to that used for syphilis studies would be highly desirable.

Conclusions reached from the first year's experience are:

1. Rh typing is definitely a public health function.
2. The minimum service offered by a public health laboratory should be typing with anti-D serum and testing for antibody formation.
3. Special tests, such as C, E, and Hr are recommended, but may be omitted depending on local conditions.
4. Mailed samples are completely reliable for Rh typing.
5. For greatest accuracy, both the tube test and the slide test should be used on all samples.
6. Rh education of physicians must be undertaken, before the full value of an Rh program can be realized.

The Laboratory Diagnosis of Tuberculosis*

MARTIN M. CUMMINGS, M.D.

Director, Tuberculosis Evaluation Laboratory, Communicable Disease Center, U. S. Public Health Service, Atlanta, Ga.

PULMONARY disease can be detected clinically and radiographically but the demonstration of tubercle bacilli in the sputum or body fluids of a patient is the surest method of diagnosing tuberculosis. As other diagnostic methods find increasing employment, there arises a greater need for demonstration of the causative microörganism. The results of other procedures, including x-ray, may be equivocal. The finding of tubercle bacilli admits of no equivocation in the diagnosis.

With the advent of mass radiography many patients have been classified as "tuberculosis suspects." The physician is confronted with the problem of deciding: First, does this pulmonary lesion represent tuberculosis? and second, if this is tuberculosis, is it "active" or "inactive"? His decision determines whether or not the patient will be sent to a sanatorium or tuberculosis hospital. Unless repeated x-ray examinations show definite changes, it is almost impossible to answer either one or both of the above questions without bacteriological aid.

Modern laboratory methods of searching for the tubercle bacillus can greatly assist in the diagnosis of tuberculous pulmonary lesions. The three procedures most widely used are: (1) microscopic search, (2) cultural techniques, and (3) animal inoculation. Nearly all types of pathological material can be examined by one or all of these methods.

MICROSCOPIC SEARCH FOR TUBERCLE BACILLI

While other means are available for detecting tubercle bacilli in pathological material, none is so easy, rapid, or readily applicable as that based on the tinctorial reactions of this bacterium. Many staining methods have been devised, but the Ziehl-Neelsen technique remains the most reliable and widely used.

Microscopic techniques, however, are not sensitive enough to be reliable when small numbers of bacilli are being sought. It has been estimated that 100,000 bacilli per ml. of sputum must be present before their detection in smear preparations is likely. Also, it is not possible to say with certainty that acid-fast and alcohol-fast microörganisms which may be seen on a slide are really tubercle bacilli. In addition, it is extremely difficult, or impossible, to differentiate microscopically nonpathogenic acid-fast microörganisms from tubercle bacilli. Because of these difficulties, numerous other methods have been devised for the purpose of revealing tubercle bacilli in pathological material. The most promising, reliable, and inexpensive of these are methods of digestion and cultivation.

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

DEMONSTRATION OF TUBERCLE BACILLI BY METHODS OF DIGESTION AND CULTIVATION

For many years it has been the practice of some laboratories to use methods thought to concentrate tubercle bacilli. Usually this consists of the addition of a digesting agent to the specimen, followed by centrifugalization and search for the bacilli in the sediment. Recently, Spendlove, *et al.*,[1] have shown that in many cases this procedure actually dilutes the specimen and makes the bacilli more difficult to find. They have shown that direct smears made by selection of choice particles, such as caseous flecks in sputum, are more efficient than smears from acid and alkali concentration techniques.

With the development of more specific and more sensitive culture media, small numbers of tubercle bacilli can be detected in pathological material by methods of cultivation. From the diagnostic viewpoint, the ideal culture medium is one which initiates rapid growth from a small number of tubercle bacilli, at the same time inhibiting the growth of contaminating microörganisms. It should be simple to prepare, yet capable of supporting the growth of different types of tubercle bacilli, at the same time allowing one to differentiate them from saprophytic acid-fast bacilli. As yet there is no artificial medium which fully meets these criteria, but much progress has been made along certain lines which leads one to believe that soon more perfect culture media for tubercle bacilli will be devised.

Among the most significant and interesting recent work along this line in the United States has been the development of a synthetic liquid medium which supports submerged, diffuse growth of small inocula of tubercle bacilli. The stages in the development of this medium are of historical and academic interest.

In 1945 Rene Dubos[2] reported the development of a liquid semi-synthetic medium which supports growth of tubercle bacilli which is submerged and diffuse, apparently because of the presence of a water-soluble ester of a long-chain fatty acid. Davis and Dubos[3] later confirmed these findings, and investigated further the effects of the synthetic lipid components. These lipids consisted of esters of sorbitol and various long-chain fatty acids (lauric, palmitic, stearic, and oleic), which are used industrially because of their surface activity, i. e., detergency, wetting properties, etc. All these compounds are characterized by their possession of both lipophilic properties (determined by the constituent long aliphatic chain of the fatty acid) and hydrophilic properties (supplied by the multiple oxygen containing groups of the alcohol). Such substances are readily adsorbed on the surfaces of the tubercle bacilli, and their wetting effect promotes diffusion of the organisms throughout the medium. This also facilitates more intimate contact between organism and environment, and thus facilitates nutrition and growth.

Of the various surface-active compounds tested, one sold commercially as "Tween 80," a polyoxyethylene derivative of sorbitan mono-oleate, was found to be most satisfactory. Tween 80 is a yellow liquid, viscous in consistency but soluble in water in all concentrations. Aqueous solutions of Tween 80 have been found to be resistant to autoclaving, but deteriorate by slow hydrolysis upon standing at room temperature for several weeks.

Davis, Dubos, *et al.*, investigated the biological properties of tubercle bacilli growing diffusely in the presence of Tween 80, and found that the three major types, human, bovine, and avian, retained their characteristic morphology and staining properties for more than a year, with repeated transfers; and their viability for periods of several months.

Both crystalline serum albumin and "fraction V" were shown by Davis and Dubos, in a subsequent publication,[4] to have a stimulating effect on the growth of tubercle bacilli in Dubos medium. Albumin alone facilitates the initiation of growth of small inocula but does not markedly increase the total amount of growth, whereas, the sorbitan monooleate (Tween 80) alone does not permit growth of the smallest inocula. The incorporation of both albumin and Tween 80 seemed to enhance multiplication; growth of the smallest inocula being detectable in 8 to 11 days. In general, serum albumin protects the tubercle bacilli and other microörganisms from the toxic action not only of long-chain fatty acids but also of many other substances: heavy metals, phenolic compounds, etc. Its major role in Dubos medium, however, is the binding of the traces of oleic acid liberated from the Tween by hydrolysis during sterilization, etc.

In a later publication Davis and Dubos[5] demonstrated beyond doubt the toxicity of unesterified fatty acid for tubercle bacilli, after developing a method[6] for extracting small quantities of fatty acid in the presence of Tween.

In addition to its protective action, the albumin was discovered to exert an undesirable effect as well. Commercial albumin (Fraction V) was found to contain small amounts of lipase which in several weeks hydrolyzed enough Tween to exceed the binding capacity of the protein which had been found to be about 2 per cent of its weight of fatty acid. Subsequent investigations[7,8] substantiated these early findings. Several methods were discovered for eliminating lipase activity from albumin.

Although Dubos and Davis never stated that this medium was devised for diagnostic use, it was apparent that investigations along these lines would soon follow. In a preliminary report, based on 165 specimens, Foley[9] concluded that this medium could be successfully used to isolate tubercle bacilli from various pathological materials. He pointed out the marked reduction in time (av. 10 days) required for the laboratory diagnosis of tuberculosis. In a second report Foley[10] summarized his experiences with the diagnostic use of this medium as shown in Table 1.

TABLE 1

Guinea Pig vs. Dubos Medium (Foley)

	Positive by				
	Guinea Pig Only		*Culture Only*		
Culture and Guinea Pig	*No.*	*Per cent*	*No.*	*Per cent*	*Mean Incubation (days)*
57	54	94.7	50	87.7	10.6

Foley also commented on his experience with the use of a modification of Dubos medium made solid with agar and recognized the difficulties involved in differentiating tubercle bacilli from saprophytic acid-fast bacilli:

"Saprophytic mycobacteria as yet cannot be sufficiently differentiated to permit the exclusive use of these media for the specific diagnosis of tuberculosis on certain kinds of material; namely, urine and gastric aspiration."

He also stated:

"As yet, too few positive specimens have been studied on the solid medium to permit analysis. The few strains isolated, as well as stock cultures of tubercle bacilli, grew as small, smooth, soft, colorless, semitransparent colonies after 7 to 10 days of incubation. Colony morphology was not unlike that of the streptococcus; markedly different from the hard, granular, opaque growth usually observed in coagulated egg media."

Goldie,[11] in 1947, reported the successful use of 2.5 per cent solution of ammonium carbonate for homogenization and concentration of tuberculous sputa which were then inoculated into Dubos medium containing 0.5 to 2 units of penicillin per ml.

Because of these encouraging reports many American laboratories have attempted to employ this medium for routine diagnostic cultures. For the most part the practice was soon abandoned for the following reasons:

1. The medium is easily contaminated. Unfortunately, when penicillin is added in concentrations high enough to be effective against contaminants, it inhibits growth of tubercle bacilli.[12,13] (See Table 2.)

TABLE 2

Examination of 5 Microscopically Positive Sputum Specimens by Two Different Cultural Methods and Guinea Pig Inoculation

Medium	*Culture showing growth of acid-fast organisms*	*Cultures showing positive results on inoculation into guinea pig*
Tween-Albumin + penicillin	0	0
Lowenstein	5	5

2. One can never be sure whether the turbidity which indicates growth is due to the presence of tubercle bacilli or other microorganisms.

3. The number of positive cultures is not greater than the number found on conventional solid egg media (see Table 3).

Totals	74	74

* From Wm. H. Maybury Sanatorium, Northville, Mich. (Courtesy—Dr. C. E. Woodfuff).

In larger series of specimens cultivated on Dubos medium in our laboratory and at the Barlow Sanatorium in Los Angeles, Calif.,[14] similar results were obtained. Because of this, the Committee on Evaluation of Laboratory Procedures of the American Trudeau Society[15] has stated that the Dubos medium in its present state is not recommended as a diagnostic medium. It seems reasonable to believe, however, that with certain modifications the Dubos medium can be developed into a medium suitable for primary isolation of tubercle bacilli. Much work is now under way with this goal in mind.

Many investigations have also been carried out attempting to simplify the more complex solid egg media (such as Petragnani's and Lowenstein-Jensen) now in wide use. The laboratory subcommittee of the American Trudeau Society[15] has devised a relatively simple egg-yolk medium which they now recommend for use in routine diagnostic laboratories.' This medium has the advantage of simplicity of preparation but has the disadvantage of supporting colony growth which is soft, creamy, and moist and, therefore, does not allow for easy differentiation of pathogenic from nonpathogenic acid-fast bacilli.

It is the experience of the Tuberculosis Evaluation Laboratory of the U. S. Public Health Service that the Jensen-Holm modification of Lowenstein's medium[16] is at present the most efficient culture medium for routine diagnostic use. Although somewhat difficult to prepare, it has the advantage of supporting the growth of human, bovine, and avian strains, and the trained bacteriologist can differentiate, with a fair degree of certainty, nonpathogenic from pathogenic acid-fast bacilli.

Colonies of human type tubercle bacilli generally appear in 12 to 25 days and because of their luxuriant growth are termed "eugonic." They are dry, friable, somewhat 'rough, and after a few weeks generally measure from 8 to 12 mm. in diameter. They assume a "cabbage" appearance and are easily detached from the surface of the me-

dium. They emulsify with difficulty.

Colonies of bovine bacilli do not grow as rapidly as the human type. They usually appear in 25 to 40 days. They are tiny, pale, smooth, pyramidal colonies. Their growth characteristics have been termed "dysgonic." They adhere to the surface of the medium and emulsify readily.

Colonies of avian bacilli generally appear in two to three weeks. They are smooth and hemispherical and often have a faint yellow or pink pigment. They are somewhat larger than bovine type colonies.

Acid-fast saprophytes appear in a few days and fortunately they are usually chromogenic. Their appearance differs from the pathogenic types in that they are soft, creamy, and usually smooth. Most strains will grow well at room temperature, whereas the tubercle bacilli require 37–38°C. for optimal growth.

Although some workers will not rely upon cultural characteristics to differentiate types, it is usually because they are not looking for these differences. With a modest amount of training, one can suspect the type of organisms from colony appearances using the Lowenstein-Jensen medium. However, final typing should always be made, resorting to the use of laboratory animals.

DEMONSTRATION OF TUBERCLE BACILLI BY ANIMAL INOCULATION

It has been pointed out that tubercle bacilli may be detected in sputum and other pathological material by careful microscopic examination and particularly by growth on culture media. Animal inoculation is a valuable additional method. This is essential in typing of strains and it may be necessary in making the diagnosis. From the diagnostic viewpoint, all urine specimens and gastric washings should be inoculated into animals as well as seeded on culture media. This is necessary because acid-fast saprophtyes are found most often in these body fluids. The smegma bacillus is a frequent inhabitant of the male genital tract, whereas many acid-fast saprophytes from food and other sources may be present in gastric washings.

Recently, experiments by Pierce and associates[17] and Patnode, *et. al.*,[12] have shown that intracerebal inoculation of susceptible strains of mice is a practical and feasible method of testing the virulence of cultures of acid-fast organisms. However, as yet, the routine use of the mouse as a primary diagnostic animal cannot be recommended. The guinea pig and rabbit are the animals of choice — the guinea pig for diagnosis of tuberculosis, human, or bovine, and the rabbit for differentiation between these two types. Fowl, of course, are needed for determination of the avian type.

Well controlled studies now indicate that cultivation techniques are as efficient for diagnosis as is animal inoculation (with the exception of urine and gastric washings). It is, therefore, recommended that all sputum specimens be cultured and that animal inoculation be resorted to only when one suspects bovine or avian type bacilli as indicated by colony characteristics.

SUMMARY

It is no longer acceptable to make a diagnosis of tuberculosis by x-ray findings alone. It is imperative, before a patient is subjected to prolonged therapy for this disease, that the diagnosis be made by recovery of tubercle bacilli from the patient's sputum or body fluids.

Microscopic demonstration of acid-fast bacilli is usually rapid and easy but one has no assurance that the organisms seen are tubercle bacilli, since acid-fast saprophytes are difficult to differentiate. Cultivation affords a more sensitive method of determining the presence of small numbers of tubercle bacilli

in pathological material. On the Lowenstein-Jensen medium the trained bacteriologist can differentiate, with a fair degree of reliability, pathogenic from nonpathogenic acid-fast bacilli. In its present state the Dubos liquid medium is not recommended for primary isolations. Animal inoculation should be performed on all urine and gastric specimens, since they more frequently contain nonpathogenic acid-fast bacilli. The mouse can be used in testing the virulence of a culture but cannot be used for primary diagnosis.

Since the advent of mass radiography, more than ever before it is imperative that laboratories be prepared to search for tubercle bacilli by methods of cultivation.

Industry's Responsibility for Worker Health*

LEO PRICE, M.D.

Director, Union Health Center, International Ladies Garment Workers Union, New York, N. Y.

THE Union Health Center furnishes a concrete example of organized labor's effort to provide medical care for workers. The International Ladies Garment Workers Union sponsors this institution, not only to take care of workers who are ill or injured, but also to prevent disability and maintain the health of workers on the job. In assisting union members handicapped by chronic disease to keep working and avoid the economic stress of disability, the institution renders a service not only to the individual, but also to the industry and the community as well.

HISTORY OF THE UNION HEALTH CENTER

The institution was founded in 1913, after a strike called attention to the sweatshop conditions existing in the industry and a Joint Board of Sanitary Control (made up of members of the union, the manufacturers, and representatives of the public) set to work to improve the hygienic conditions of the factories. A tuberculosis control program was instituted, sickness insurance inaugurated, and the Union Health Center began to provide medical service, primarily to offer preventive medicine at a convenient time and place and at a cost the worker could pay.

After 30 years, through the union members' own efforts and financing, the institution developed so that it provided about 125,000 services a year in 18 different medical specialties and diagnostic facilities. In 1944 the first employer contributions to the health and welfare funds for garment workers enabled the Center to begin an unprecedented program of expansion, and in 1948, about 450,000 services will have been rendered. The ratio of increase in the actual medical services rendered remained constant among the various specialties and general medicine. However, it was noticed that the ratio of the use of diagnostic facilities to the medical services showed a striking increase, indicating that a better quality of medical care is possible when the cost to the patient is no longer a limiting factor.

The Center occupies six floors of a 27 story building in the garment district of New York City. Its uninterrupted existence and its success in providing good medical care have been primarily due to the fact that it has always been under medical direction. A Medical Council helps formulate its policies and a Medical Board, composed of the heads of each medical service, meets periodically with the staff to consider administrative and scientific problems. Ten full-time physicians coördinate the work of about 125 visiting physicians who man the clinics, certify the disability claims, and direct health surveys. There are also 210 other employees, among whom are 32 nurses, 27 technicians, and 5 pharmacists.

* Presented before the International Association of Industrial Accident Boards and Commissions' Convention in New York, September 15, 1948.

SICKNESS INSURANCE IN THE LADIES GARMENT INDUSTRY

Before 1944, sickness insurance was financed by a nominal premium of $4.20 a year, paid by each member covered. This premium was far below those of many commercial sickness and accident policies. Further, the members of the ILGWU would be considered uninsurable by most underwriters because of the advanced age of the male workers (the average age is over 50) and the high percentage (85 per cent) of female workers.

With such low premiums it was necessary to have strict medical administration of the insurance fund. Therefore, the Health Center then examined each new member who applied for sickness insurance. Since 1945, contribution to the fund by the employers of the industry has made it possible to offer a wider scope of insurance to every union member, regardless of state of health, age, or sex.

Data accumulated in the year 1944, when sickness insurance was maintained wholly by the members, showed that the frequency of claims in that year was 5.7 per cent of the membership insured. The number of disability days averaged 42.3 per claim and 1.83 per cent of the insured members were hospitalized.

In 1947, when the exclusion clauses on gynecological, psychoneurotic, and other conditions were removed, the frequency of claims rose to 10.4 per cent, but disability days per claim dropped to 41.4. Hospital cases rose to 2.56 per cent.

PHYSICAL IMPAIRMENT NOT INCOMPATIBLE WITH PRODUCTIVITY

The value of a medical service program for workers is apparent from some of the data recently acquired, which confirms previous studies of the extent of chronic illnesses occurring among garment workers. We can emphasize that the physical impairment encountered among the skilled workers who are patients at the Health Center apparently does not lower their productivity. The figures covering the frequency of claims and the period of disability do not reflect the extent of the presence of chronic diseases in this group.

Study of a random sample of 5,000 claims for disability made by garment workers in 1947 reveals that the most common cause for disability is diseases of the heart and the circulatory system. These conditions cause the highest number of days lost by the average invalided worker in this industry—51.7 days a year.

The diseases of the respiratory system, which usually occur with the greatest frequency among the general population of this country, were second on the list, representing 14.7 per cent of the total. The average number of days lost through these conditions was less than half of the other disabling conditions—23.7 days per person. Eleven hundred and twenty-five workers were disabled by tumors, of which 415 were cancers or other malignant new growths.

It is estimated that among the 19,750 who received disability claims in 1947, 818,000 working days were lost. Therefore, the average number of days lost by each of the 180,000 insured members of the ladies garment workers union in New York City was 4.3 days in that year—a much lower figure than is found among the general population of this country.

These morbidity data were acquired through the use of the U. S. Public Health Service *Diagnostic Code for Use in Tabulating Morbidity Statistics* (1944). Estimates were made on the basis of the average sickness insurance program functioning among the 32 local unions of the ILGWU in New York City, which offers, as a rule, cash benefits for 13 week periods. Probably other factors influence this exceedingly

TABLE 1

Distribution of Disease among 19,750 Disability Claims, 1947, at the Union Health Center

(Estimated on basis of a random sample of 5,000 claims)

Disease Groups	*Per cent of Total*	*Average Number of Days Lost*	*Number of Patients*	*Total Number of Days Lost*
Heart and Circulatory System	15.2	51.7	3,000	155,000
Respiratory System	14.7	23.7	2,900	68,700
Digestive System	11.8	44.8	2,330	104,300
Genito-Urinary System	10.4	48.7	2,055	100,000
Bones and Organs of Movement	9.9	44.1	1,960	86,500
Neoplasms, malignant and non-malignant	5.7	50.3	1,125	56,000
Others	32 3	38.7	6,380	247,000
Total	100 0	41.4	19,750	818,100

low estimated sickness absenteeism, such as the seasonal nature of the industry. However, the figure seems to be valid for ladies garment workers, in view of the large number of employed persons covered and the constancy of this rate over a period of years.

MEDICAL SERVICE MINIMIZES EFFECT OF TOTAL AND PARTIAL DISABILITIES

The necessity for industry to bear the cost of industrial accidents and health hazards has become an accepted concept. The Union Health Center takes this concept one step further by demonstrating that the practice of preventive medicine for the maintenance of the health of workers can be done economically, efficiently, and to the advantage of labor, management and the community, at a nominal cost to industry.

From the experience of this institution it can be seen that where medical service can be extended to persons disabled by minor or major handicaps, far less loss of working time will ensue. A person who has suffered injury through accident or illness, or who is handicapped by chronic illness which disables him at periodic intervals, is prone to worry and to a feeling of insecurity which threatens his ability to work. Without the support of constant medical service, a minor physical handicap is too often aggravated by an exaggerated mental distress which causes a prolonged disability requiring extensive and expensive medical attention. Often, older age workers with physical impairments have more highly developed skills and are more dependable than the younger, healthier workers who feel more secure and less eager to maintain a position in the industry.

The attitude toward absenteeism on the part of labor and management clashes because management prefers to employ healthy workers to minimize the possibility of absenteeism, while labor tends to stress the need for keeping handicapped workers on the job. Absenteeism will be decreased by the use of health and welfare funds to provide medical care to maintain the health of workers.

REHABILITATION OF THE PHYSICALLY IMPAIRED

In the social security and compensable disability field there have been, unfortunately, large gaps in the provision of the necessary means of rehabilitation in chronic illnesses. This is evident in tuberculosis, arthritis, heart disease, and neurological conditions, all of which are now receiving the attention of the National Health Institutes.

In these conditions the costs of rehabilitation are beyond the capacity of ordinary wage earners. Also, the implications of the disabilities caused by the disease produce fear in the victim as well as in the employer. Thus, the

economic problem is so great that no individual worker or employer can solve it without assistance.

Legislation which will protect everyone is necessary, with the government offering aid for a program supporting the rehabilitation of citizens, so that there will be no fear of further compensation or economic drain upon the insurance company or the individual employer. In this way prejudice against the hiring of physically impaired workers may be overcome. Undue fear of compensation claims, which prevents the utilization of skilled handicapped workers, is to the detriment of the victim and the industry.

Today's trend is toward recognition of the principle that a worker's life and health are exposed to physical deterioration and destruction in industry, just as machinery is exposed to wear and tear, breakage, and depreciation. Perhaps there is no better impetus to the acceptance of this principle than the recent development of health and welfare programs in industry.

The mine workers have announced an extensive proposed program, and the ILGWU has a 35 year record of providing medical service and social security benefits for its members. Already numerous other unions are following this pattern. Three million workers in the United States are now protected by health and welfare funds involving 300 million dollars.

This trend in industry parallels a movement for state governments to take over some phases of social insurance through the extension of compensation laws. Rhode Island was the first state to compensate workers for disabilities due to non-occupational illnesses as well as for occupational disabilities. California and New Jersey have also taken this step.

The vital question before us today is: Will the states undertake, as Rhode Island has, complete (monopolistic) control of the administration and distribution of compensation for disability due to any sickness? Or, as in California and New Jersey, will the states supervise the work of existing insurance companies, industries, and trade unions which have well established social insurance programs?

Regardless of how these questions may be settled, it is evident that industry, both labor and management, are beginning to attack the problem effectively.

REORGANIZATION OF THE HEALTH SERVICES OF THE FEDERAL GOVERNMENT

ON November 30, 1948, a Committee on Federal Medical Services, under the Chairmanship of Tracy S. Voorhees, made a report to Herbert Hoover, Chairman of the Commission on Organization of the Executive Branch of the Government, which has been briefly reviewed in our columns.[1] The subcommittee which dealt specifically with the problems of preventive medicine and public health was under the Chairmanship of Hugh R. Leavell, now Chairman of the Executive Board of the A.P.H.A.

It will be recalled that the Commission assumed the creation of a new Cabinet Department embracing health, education, and social security. It recommends that within this department there be created a National Bureau of Health with a professional career officer as Director General, reporting directly to the secretary of the department. It proposes within this bureau three major divisions dealing, respectively, with Medical Care, Public Health, and Research and Training.

The Medical Care Division would administer all general hospitals of the armed services and most station hospitals, except those at outlying posts[2]; the hospitals of the present Public Health Service; and St. Elizabeths Hospital; and would discharge all medical functions of the Veterans Administration, intramural and extramural.

The Public Health Division would include the functions of the Bureau of State Services, the quarantine activities, the Biologics Control Laboratory, and the Offices of Sanitation, Engineering, and Dentistry of the U. S. Public Health Service; and also the duties of the present Food and Drug Administration. Its major functions would be to administer grants-in-aid, to conduct a clearing house of information on all public health activities; and to regulate interstate commerce in foods, drugs, and medicines.

The Division of Research and Training would include the direction of the National Institutes of Health and administration of grants-in-aid in its field.[3] The

strongest emphasis is laid throughout the reports of the committee on the importance of prevention—not only for the benefit of the people as a whole but for reduction in the cost of medical care to the federal government itself, which now provides such care to between one-sixth and one-seventh of the population of the United States.

The scope of these recommendations is radical and far-reaching. They will no doubt be opposed—as all attempts to reorganize the machinery of federal government have always been opposed—by individuals and groups who fear damage to traditional power and prestige. They will, no doubt, be subject to criticism by others who believe that parts of the program are basically unsound. Such criticism should be welcomed, for no administrative proposal is ever perfect.

The problem is being studied by appropriate organs of our Association; and the A.P.H.A. will be duly represented when bills to implement the program are introduced and called for hearings. Meanwhile, the subject should be carefully considered by our membership, and comments submitted to our officers so that the wisest possible decisions may be reached.

In any case, Mr. Voorhees and his committee deserve our gratitude for their courageous and constructive attack on a serious and vital problem; and particularly, for their emphasis on the fact that the solution of that problem depends on prevention rather than cure and requires extension of the basic research on which progress in preventive medicine must rest.

2. Except that each of the Armed Services will maintain one medical and teaching hospital and all overseas hospitals.
3. It is suggested that the Children's Bureau should function as a staff unit, directly responsible to the secretary of the department; and that grants-in-aid for maternal and child health and for crippled children should be administered by this bureau for the present. The administration of such grants—but not the other functions of the Children's Bureau—would be transferred to the National Bureau of Health after three years.

DOROTHEA LYNDE DIX

THERE is a strong movement on foot this spring to secure the election of Dorothea Lynde Dix to the Hall of Fame, when the choice of the next group of candidates for this honor takes place in 1950. It is a movement which should have the active support of the public health profession. Oliver Wendell Holmes, W. T. G. Morton, and Walter Reed are the only representatives of the health field in the present roster of the Hall.[1]

Dorothea Dix was the grandchild of an active and vigorous physician and apothecary. Her family lived in Boston, although she was born on a visit to Maine in 1802. After the death of her father, in 1821, she lived with her grandmother in Boston and tutored the children of William Ellery Channing (who was a major influence in her life), and organized a successful private school. In 1836 she suffered a complete physical and nervous collapse; but gradually recovered. In 1841, she volunteered to teach a class organized for women convicts in the East Cambridge jail; and this proved the turning point of her career.

In the jails and almshouses of this period, the criminal, the indigent, and the mentally diseased were indiscriminately huddled together under physical and psychological conditions of a barbarity which it is difficult for us to realize today. The revelation of conditions in East Cambridge roused Dorothea Dix to action.

Notebook in hand, she visited jails and almshouses from the Berkshires to Cape Cod and prepared a memorial to the Legislature calling attention to "the present state of insane persons confined within this Commonwealth, in cages, closets, cellars, stalls, pens; chained, naked, beaten with rods, and lashed into obedience." Her overwhelming mass of evidence and her fervid eloquence prevailed; and a bill was passed providing greatly increased facilities for the care of the insane in the Worcester Hospital.

As soon as this measure passed, Miss Dix began to extend her program to other states. She made a first hand study of conditions and presented memorials to the legislatures in New York, Rhode Island, New Jersey, Pennsylvania, Kentucky, Louisiana, Ohio, Tennessee, North Carolina, Alabama, Mississippi, and other states. She underwent untold hardships and hazards in her journeyings. Once when passing through a Michigan forest, she noted that the lad who was driving her had a brace of pistols which she took away from him to avoid violence. Soon thereafter, a man rushed into the road and demanded her purse. "Are you not ashamed to rob a woman?" she said, "I have but little money and that I want to defray my expenses in visiting prisons and poorhouses, and occasionally in giving to objects of charity." The expression of the highwayman changed and he became "deathly pale." He recognized the voice he had heard lecturing to prisoners in a Philadelphia penitentiary; and Miss Dix was obliged to force some money on him "to support you until you can get into honest employment."

Dorothea Dix's selfless passion for humanity triumphed over hostile legislatures as over menacing bandits. Eleven states, by 1850, had established or enlarged hospitals for the insane at her behest, including the Butler Hospital of Rhode Island and the first state hospital of New Jersey at Trenton.

After the decade of this whirlwind state campaign, Miss Dix began to cast her eyes on Washington and on June 27, 1848, a memorial prepared by her was presented to the Congress, calling for the appropriation of five million acres of public land, to be sold and the proceeds distributed among the states for the care of the insane. Shelved in the 1849 Session, this bill (with an increase to 12,500,000 acres of land) was reintroduced in 1850 and expanded to cover the indigent blind, deaf and dumb, as well as the indigent insane. In one session of this Congress the House passed the bill and the Senate defeated it; in a second session the process was reversed. In the 1854 Congress Miss Dix and her friends began the fight again. This time the bill passed both houses; only to be vetoed by President Franklin Pierce on the grounds—prophetic of much future discussion of similar issues—that "if Congress have power to make provision for indigent insane without the limits of this District, it has the same power to provide for the indigent who are not insane and thus to transfer to the federal government the charge of all the poor in all the States. . . . The fountains of charity will be dried up at home, and the several States, instead of bestowing their own means on the social wants of their own people, may themselves become humble suppliants for the bounty of the federal government, reversing their true relation to this Union."

It was a century later, in 1946, that the National Mental Health Act was passed, making the dreams of Dorothea Dix a reality on the federal level. What she had accomplished in the states, however, constituted probably the greatest forward step in the care of the insane ever accomplished by any individual on this continent.

The admission of Dorothea Lynde Dix to the Hall of Fame would do more than render just honor to a great American. It would call attention to the impor-

tance of carrying forward the banner which she raised a century ago; and at a moment when the advancement of the cause she served is particularly timely.

Progress in the field of mental hygiene in the United States has been curiously associated with fifty year cycles. It was at the end of the 18th century that Benjamin Rush, for the first time on this continent, preached the importance of reasonable and humane care and treatment of the insane. It was in the middle of the 19th century that Dorothea Dix began to make Rush's vision a reality. It was in the first decade of the 20th century that Clifford W. Beers reawakened public interest in this problem and founded the National Committee for Mental Hygiene. Today we are in a fourth period of great potential progress. The Second World War demonstrated the vital importance of mental hygiene through the revelation by draft examinations of the extent of the problem, and by the intelligent attitudes of the medical departments of the Armed Forces indicated the curability of a large proportion of emotional disabilities. Military experience of the First World War made us stop talking and begin doing something about venereal diseases. The Second World War, with the reënforcement of the National Mental Health Act, can accomplish the same sort of change in public attitudes with regard to the emotional disorders.

We know that our institutions for the care of advanced mental disease are better than those which Dorothea Dix and Clifford Beers denounced; but that they are still—for the most part—badly planned, undermanned, under-financed—disgraces to our civilization. We know that mental hygiene clinics and child guidance clinics are found here and there, doing the finest type of preventive work; but that the number of such essential facilities available is only a small fraction of what is needed to meet basic community needs.

Our best tribute to the memory of Dorothea Lynde Dix should be to give the cause of mental hygiene, which she promoted so gallantly and with such success, the support which will bring it to its appropriate place in our community program for the promotion of the public health.

RESEARCH ON POLIOMYELITIS

THE National Foundation for Infantile Paralysis was organized, in 1938, primarily for the purpose of study and research in connection with the disease from which its great founder suffered. In the very next year, however, it entered the field of direct assistance in the actual care of patients suffering from poliomyelitis. In 1948, with the serious epidemic in certain areas (with 1,122 cases reported to the U. S. Public Health Service in the week of highest incidence), this aspect of the work of the Foundation was preëminent in the public eye. Between January and October the national headquarters, from its 50 per cent share of the March of Dimes campaign, provided about four million dollars for direct relief service to chapters whose local funds had been exhausted. This financial aid, the provision of hospital supplies and equipment, and the training and assignment of specialized personnel (doctors, nurses, nursing aides, physical therapists, etc.) have, of course, been invaluable in dealing with epidemics.

Of even greater potential importance, however, is the comprehensive program of basic research which the N.F.I.P. continues to foster and whose significance the general public is apt to overlook. In the last seven months of 1947 (for which full reports are now available) the Foundation provided grants of three-quarters of a million dollars to over 30 university and hospital laboratories for research projects. About one-third of this sum was for studies on the prevention and treatment of the aftereffects of the disease, two-thirds for research on the virus and its relations to the human and animal body. Under the latter heading are included projects dealing with diagnostic methods, with the differentiation of strains of the virus and with methods of spread of the disease on the one hand; and, on the other, with host problems, such as the reproduction of the virus in the body, the chemistry of reacting mammalian tissues, the response of nerve tissues to invasion, the mechanisms of immunization, the influence of genetic strains of experimental animals and their nutrition upon the processes involved. All of these studies should be of interest, and will contribute to fundamental scientific knowledge if not to the control of poliomyelitis; but through such a diversified program, somewhere, some day, the great moment will come. The key will be found when we know why the majority of persons in contact with the virus are unscathed while the minority suffer from clinical disease. This is the heart of the issue and it is a problem of biochemistry in a broad sense of the term.

When the secret is at last revealed, it will come as a result of such basic researches as the N.F.I.P. is now making possible.

Clearing House on Public Health Salary Information

Recommended Salary Minimums for Public Health Physicians *

The holding and procurement of competent personnel is one of the most difficult and crucial problems in public health administration today. An acute personnel shortage exists and low salaries paid professional public health workers by most public health agencies is a major factor responsible for this shortage.

Illustrative of the personnel shortage facing almost all health agencies is the experience of the American Public Health Association's Vocational Counseling and Placement Service. As of October 1, 1948, 766 vacant positions were listed in contrast to 91 applicants for these positions. A study by the U. S. Public Health Service [1] revealed 1,847 vacancies among health agencies in 12 states in November, 1947, and meantime the situation appears to have grown worse and not better. The field of public health has been expanding rapidly, creating a large demand for additional personnel, and this expansion will continue to aggravate the personnel shortage.

In spite of the salary increases granted recently to some agencies, many public health workers are worse off now than before the war. It has been shown in one study [2] that it requires $9,819 in 1948 to buy what $5,000 would buy in 1939 for a family of four; and according to the *Bureau of Labor Statistics Consumers Index*,[3] the cost of living has increased from August 15, 1939, to August 15, 1948, by 76 per cent.

The proportionate increase of salaries of professional public health workers has been much less than this. The figures vary from place to place, but the following examples are typical of the discrepancy. In one state with a good public health program, the salaries of medical health officers increased only 37 per cent between 1940 and 1948.[4] In another state the salaries of all state employees increased only 28 per cent between 1939 and 1948.[5] Obviously the purchasing power of these salaries decreased during those years; meantime, in these states as in most states, the public health program has steadily grown, which means the professional workers are carrying heavier responsibility for less real income.

In contrast to these inadequate salary increases, wage earnings in manufacturing industries increased by 100 per cent and the national per capita income by 140 per cent between 1940 and 1948.

It is generally recognized that a great discrepancy exists between the incomes of full-time public health physicians and those in private practice, although no substantiated figures are available for comparison. It is significant that the average asking salary of physicians seeking work with the American Public Health Association's Vocational Counseling and Placement Service is considerably higher than the average salary offered. It is to be noted that most graduate physicians go into private practice rather than public health work.

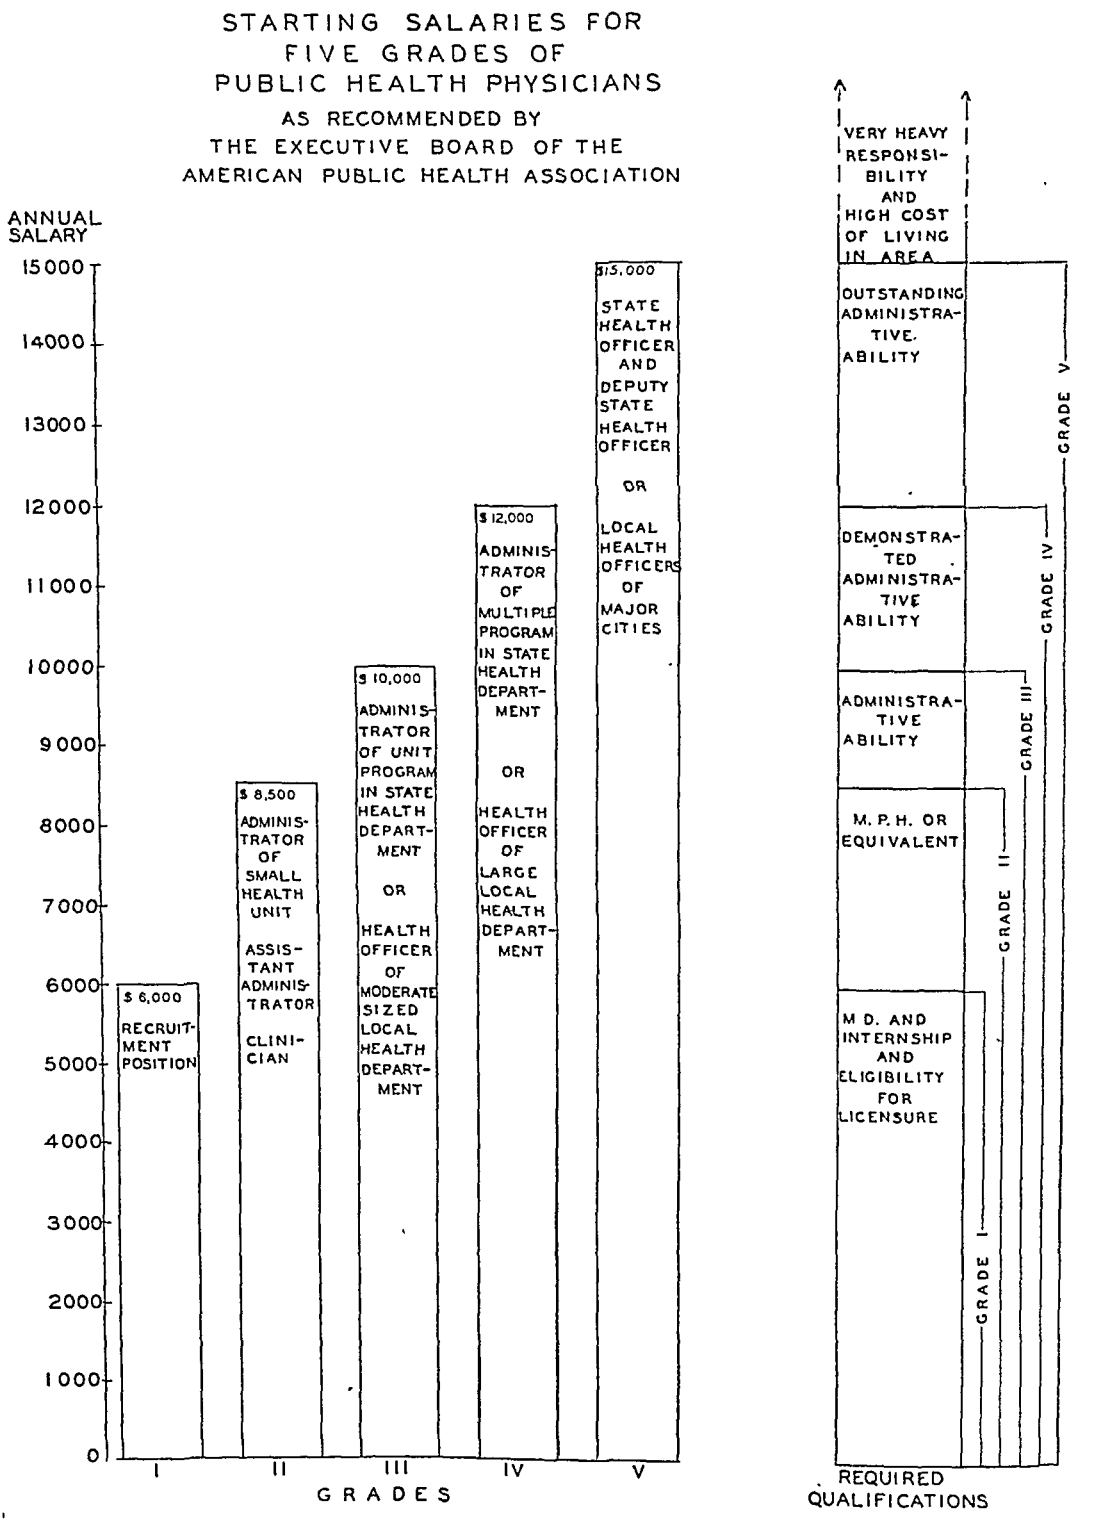
The median salary of full-time public health physicians in the state agencies (exclusive of state health officers) in 1948 fell in the range $6,000 to $6,400 [6]; and those in local health agencies in the range of $6,480 to $6,720.[7] These salaries appear to be much less than the net annual income of a good general

* Approved by the Executive Board of the American Public Health Association, January 28, 1949.

practitioner in most areas in the United States.

However, the experienced public health physician with special training (an M.P.H. academic degree) and/or demonstrated ability to administer public health programs is now recognized as a medical specialist. As evidence of this, the armed forces and the U. S. Public Health Service established an Interim Board to recognize public health as a specialty of medicine. An American Board of Preventive Medicine and Public Health has been set up. The salary of a public health physician should reflect his specialty training and attainments.

Legal restrictions in many governmental jurisdictions freeze the medical health officer in a salary range with other department heads (or sometimes below them), few of whom must have the training equivalent to that of a qualified health officer, with salaries of subordinate professional personnel below that of the health officer. Thus the median salary of municipal health officers ranged from $3,900 in cities of 10,000 to 25,000 population to $10,000 in cities over 500,000 according to the *Municipal Year Book 1948*.[8] In each of the six population groups in that study the median salary of health officers was considerably below the median salary of the superintendent of schools, ranging from 64 per cent in cities of 250,000 to 500,000 to 79 per cent in cities over 500,000 population. It is essential that salary boards and appropriating bodies recognize in their salary schedules the special training, experience, and competence required of professional public health workers.



For other but related reasons public health positions often lack attractiveness. Salary increments, when provided, have not exceeded 5 years generally, which may result in the employee, who has reached the maximum salary, looking elsewhere for a position. His value to the organization, however, usually will increase if he stays with an agency well beyond the 5 year period. Security of tenure for competent personnel, retirement plans, sick leave, and vacation periods have been inadequate in many instances.

An effective recruiting program is essential to fill existing vacancies and positions being newly established, but such a program can succeed in substantial measure only if salaries and related prerequisites are commensurate with the training and experience required of the employee and bear a reasonable relationship to the earnings available in private practice or other full-time employment by similarly qualified persons. Lacking this, not only will recruitment be inadequate, but competent personnel will continue to desert public health for other more remunerative positions, as they now are doing.

The Executive Board of the American Public Health Association, well aware that the public is faced with the urgent necessity of holding and recruiting competent personnel for public health positions, and that improvement in salaries paid and personnel practices is essential to achieve these needs, has recognized the facts set forth above and has endorsed the recommendations and graphic presentation which were prepared by the Subcommittee on Salary Study and approved by the Committee on Professional Education.

ADOPTED JANUARY 28, 1949

RECOMMENDED SALARY MINIMUMS FOR FIVE GRADES OF PUBLIC HEALTH PHYSICIANS

The compensation for physicians employed full time by health agencies in the United States in 1948 should be adjusted to not less than the following scales which take into account the degree of responsibility in various positions, the training and experience required of the physicians, the necessity for maintaining professional standing in a community, and the increasing cost of living.

1. Physicians employed in a full-time position for training in public health should receive an annual salary of at least $6,000 if they have an M.D. degree from a recognized medical school, have completed an internship, and are eligible for licensure in the state in which they work.

2. Physicians employed in a full-time position as a clinician, health officer of a small unit, or an assistant administrator, should receive an annual salary of at least $8,500 if they have the following basic qualifications:

a. A degree Doctor of Medicine from a recognized medical school.

b. One year of internship and eligibility for licensure.

c. A Master's degree in Public Health (which includes some field experience) or demonstrated knowledge and experience equivalent to that represented by this degree.

3. Physicians with these basic qualifications who in their past experience have shown administrative ability should receive an annual salary of at least $10,000 if they carry the responsibility for administering a single program in a state health agency or a large local health agency (e.g., program for cancer control, mental hygiene, tuberculosis, or crippled children, etc.); or serve as health officer of a moderate sized local health unit, or carry equivalent responsibility.

4. Physicians with the basic qualifications and demonstrated ability to administer responsible public health programs should receive an annual salary of at least $12,000 if they carry heavy responsibility such as administering multiple programs in a state health agency (e.g., directors of local health administration, preventable disease control); or serve as health officer of a large local health unit, or carry equivalent responsibility.

5. Physicians with these basic qualifications and outstanding demonstrated ability to administer public health programs should receive an annual salary of at least $15,000 to $20,000 if they carry great responsibility in positions, such as the health officers and deputies of our states, major cities, and very large local units carry.

In those areas in the United States where the cost of living is higher and/or the public health physicians carry unusually heavy responsibility, higher entrance salary levels are recommended. Salaries, when adequate, should be adjusted proportionately as the cost of living materially changes.

Attention is directed to the necessity for pay increments to recognize the increasing value of service usually given to an organization by public health physicians holding positions in which no further advancement is possible as their length of service increases. Most plans today reach a maximum automatically within a few years. A graded plan of pay increments which extends throughout the period of employment should be adopted for meritorious service.

All official agencies should have an adequate merit system for the selection and promotion of competent personnel and the protection of their tenure of employment, and for the removal of incompetent personnel. Adequate plans for retirement, vacation and sick leave, and an adequate scale of payment for travel and other expenses are essential.

The Executive Board recognizes that the salaries recommended above are considerably higher than the medians now paid for comparable positions; however, the Board is well aware of the fact that the better qualified candidates for positions in public health are demanding salaries equivalent to or in excess of those recommended, and that an increasing number of employers are offering such salaries.

A STATEMENT ON THE RELATIONSHIPS OF THE VOLUNTARY HEALTH AGENCIES TO THE SCHOOL HEALTH PROGRAM *

SEVERAL groups either legally or through common interest share in the school health program. The growth of the program and of the health knowledge upon which it is based is almost staggering. Only through the effective relationship of all groups with important contributions to make, can the school health program approach its goal the best possible health for all children now and throughout their lives.

School authorities by law carry the ultimate responsibility of all programs conducted in the schools. This includes the school health program. Since the control of communicable disease is a part of every school program and is frequently by law the responsibility of the public health department, and since in some states departments of health are responsible by law for medical examinations and follow-up, the latter to the extent set by local statute shares the responsibility of the school health program.

There are many groups without legal responsibility for the school health program which nevertheless have a vital interest in and contribution to make, in whole or in part, to the school health program. Important among these are the medical and dental professions which have through the years given impetus and sound advice toward the continued improvement of school health programs.

Another essential group is the voluntary agency composed of interested citizens, both lay and professional. These agencies are frequently concerned with some special aspect of health. This interest, if properly placed and properly handled, has a part in the total school health program. The aim of the voluntary health agency interested in the school age child is to help make possible for boys and girls lives of usefulness unhampered by illness or poor health. The effectiveness of the voluntary health agency's assistance to schools depends to a large degree upon the mutual understanding of the responsibilities, limitations, and contributions peculiar to each.

A. *Guiding principles in interrelationships between voluntary health agencies and the schools:*

1. School authorities have the legal responsibility for all school programs. The unique function of the school is education.
2. Voluntary health agencies accept this. They also recognize that school age is an excellent learning age. Moreover, their money comes from the community with the trust that it be spent to the best advantage. For these three reasons they strive, logically, to have what they consider important learning material included in this age period. School administrators should recognize that voluntary health agencies have the responsibility and the right to offer and to urge the use of their services. Voluntary health agencies should recognize that the school authorities have the choice of accepting or refusing these services. A coöperative attitude on the part of both parties leads to

* This report involved the coöperative efforts of the School Health Section of the American Public Health Association and the American Association for Health, Physical Education, and Recreation. The statement was prepared by Mrs. Elizabeth M. Semenoff, Director, School Health Education Department, District of Columbia Tuberculosis Association, Washington, D. C., and Ben W. Miller, former Executive Secretary, AAHPER. A request for the coöperative project was made by Mr. Miller and was approved by the School Health Section Council in November, 1946. The appointment of Mrs. Semenoff as a member and representative of the Section to work with Mr. Miller was approved in January, 1947, by the Executive Board of the American Public Health Association. The statement was presented in October, 1947, and approved the following month by the School Health Section Council of the A.P.H.A. In January, 1948, the statement was approved via mail ballot by the Board of Directors of the AAHPER.

the most effective use of the services offered.

3. It is very desirable that personnel working with the schools in any phase of education for health be acquainted with the problems of school administration and classroom instruction and have an understanding of acceptable policies and practices in health education.
4. While voluntary health agencies may contribute to any part of the school health program their most valuable services are usually in the field of health instruction.
5. All efforts in the health instruction of children in school must be channeled through the regularly constituted educational authorities, in coöperation with any other agencies which may also be concerned. This should apply to any situation whether on the federal, state, or local level.
6. The voluntary health agency should never attempt to superimpose a fixed plan on any individual school system, or part of the system, but should work with school personnel for the desired goal.
7. Health education materials offered by voluntary health agencies for the elementary grades must be in harmony with the mental and emotional stage of development of the children concerned. Only those public health problems which touch the child's daily health practices such as the use of quarantine in the control of communicable diseases in children come within his range of interest and understanding. Learning experiences which have direct bearing on his personal health are basically important for these grades. The child in these years is interested in health, not disease
8. In the secondary schools education related to special diseases or special health problems should be integrated into the health course and into such general courses as human biology and general science. It is not acceptable educational practice that programs dealing with specific health problems such as nutrition, cancer, tuberculosis, venereal disease, and first aid be set up as a separate or extra subject. So isolated, one aspect of health has little or no chance of assuming its proper place in the individual's total health learning.
9. The voluntary agency must have a clear understanding with the educational authorities as to suitability and distribution to school personnel of materials they provide. Sound educational policy involves mutual agreement that the provision of educational materials to schools by voluntary agencies be kept separate from their direct fund-raising campaigns.
10. The voluntary health agency should be familiar with the extent and quality of the teachers' education in health.

B. *Types of aid acceptable to school authorities which voluntary agencies can give to the school health program:*

1. Up to date, accurate information on the agency's special health interests. Such assistance should be not only welcomed but asked for by school personnel, who cannot expect to be able to keep up with all phases of the rapidly increasing health knowledge.
2. Teaching tools, such as pamphlets, posters, charts, graphs, films, film strips and slides, exhibits. Such material must be accurate, clear in concept, attractive, and effective, with its purpose solely educational.
3. Suggested teaching units. It is recommended that in the preparation of teaching units the voluntary health agency make use of experienced teachers so that the material is adjusted properly to grade levels and needs.
4. *Consultation services.*
5. Personnel assigned to educational authorities to work under their jurisdiction.
6. Assistance in the formation of school health councils and coördination of the school health councils with the community health council.
7. Qualified personnel provided to demonstrate a health education program or part thereof, to experiment in new types of programs or to fill the temporary lack of adequate school personnel.
8. Coöperation in the inservice course in health education either in the form of funds or personnel. Such courses should be developed coöperatively with school authorities, especially those having to do with teacher preparation and certification.
9. Scholarships for education in health education.
10. Financial assistance and/or leadership in special projects, such as workshops.
11. Individual conferences with teachers possibly including demonstration teaching of selected health units by a qualified health educator.
12. Guidance in helping teachers to understand classroom observations and/or measurements, non-diagnostic or medical

in nature and in helping to detect, and refer children with signs of impaired health.

13. Guidance for teachers or parents in learning the use of non-medical non-diagnostic screening tests, such as vision and hearing testing, and weighing and measuring.
14. Educational presentations to classroom groups, supplementary or summarizing in nature. These are not to take the place of classroom teaching, which is not to be provided by the voluntary agency except for possible demonstration teaching of a health lesson.
15. Parent health education.
16. Leadership in parent or teacher study groups.
17. Information of general advances in health knowledge and practice for school administrators and teachers.
18. Securing the interest and coöperation of other community groups to participate in the school health program, e.g., conferences and medical and/or educational presentations for teacher groups.
19. Interpreting school health program and unmet needs to the community and stimulating action if desirable.

Credit Lines

THE DIAMOND JUBILEE OF AMERICAN NURSING

Those concerned with the recruitment of public health personnel, and in particular with the nursing shortage, will have noted the well planned effort under the sponsorship of the American Nurses Association for the Diamond Jubilee of Nursing, signalizing the 75th anniversary of professional nursing in the United States. A week in November was set aside for public attention to this subject.

Recruitment for public health nursing is not standardized or stereotyped and in view of the fact that this represents the best financed recruitment effort in public health, the methods employed are worthy of note. Further information may be obtained from the American Nurses Association, 1790 Broadway, New York 19.

A national committee of sponsors for the Diamond Jubilee included the President of the United States, the President of the Rockefeller Foundation, a series of university presidents, the presidents of large professional societies, and other American leaders, including the Surgeons General and other headline names. The information was published with a build-up of Linda Richards, "America's First Professional Nurse" who graduated in nursing from the New England Hospital for Women and Children, Boston, in 1873. Her career as organizer of nursing schools and leader of nursing progress is chronologically presented to the time of her death in 1930.

Accompanying this brochure are three fact sheets, one on legal control, one on nursing distribution, and one on economic security. These are presented in question and answer form and should be provocative to other professions seeking to recruit personnel through similar devices.

Supplementing the foregoing is a series of four pamphlets entitled, 1. "An appeal for Public Coöperation to Resolve the Nursing Crisis"; 2. "American Health Standards Demand Legal Control of Nursing"; 3. "Will You Get Your Share of Professional Nursing Care?"; 4. "A Crisis in Nursing Care Threatens the American People."

Several posters were prepared for the occasion, together with a suggested bibliography on nursing and addresses by various leaders, including Miss Pearl McIver, President of the American Nurses Association.

All in all this has been a creditable approach which ought to have a critical evaluation in the light of results produced so that subsequent efforts of this kind may be even more effective.

FROM A WORKER'S IDEA TO A NATIONAL SAFETY CLUB

The story of the Wise Owls Club has a new gimmick. It didn't originate in a high powered publicity office but in the mind of a grinder in the cleaning room of a foundry—Joe Folks by name, supposedly. Knowing how the Caterpillar Club made the army air force safety conscious, he suggested to the American Car and Foundry Company for which he works, that the idea could be adapted to the peacetime problems of eye safety in industry.

The safety department picked up the idea, designed a small gold owl wearing goggles and found 76 men in ACF plants in six states as charter members, all of whom had saved an eye because of wearing eye goggles in accidents that would

otherwise have been fatal to one or both eyes. This was in April, 1947. By August, 1948, 66 men had been added as charter members at a net saving in workmen's compensation of more than $150,000. In the meantime, the cost of the program was only $33,000.

At this point, American Car and Foundry decided the idea was too good to hoard and turned it over to the National Society for the Prevention of Blindness which is now spreading Wise Owl Clubs throughout industry. It supplies membership pins and certificates for charter members as they become eligible for $2.00 each. For information about a *Wise Owls Club in Your Plant,* write National Society for the Prevention of Blindness, 1790 Broadway, New York 19.

PAMPHLET ON BRUCELLOSIS

The National Society for Crippled Children and Adults does not hold to the conventional definition of "crippling." It has recently published a pamphlet "The Crippler in Disguise" which is the story of Undulant Fever in America. The material is of good quality, is well illustrated and should be widely known to health educators and health officers. National Society for Crippled Children and Adults, 11 South La Salle St., Chicago 3.

FLUORIDES AND WATER SUPPLIES

The pros and cons plus a good historical outline of the addition of fluorides to drinking water for the prevention of caries appears in "Shall Fluoride Be Added to Public Water Supplies?" by Harry A. Faber, in the November, 1948 issue of *Water & Sewage Works.* Mr. Faber doesn't attempt to answer the question, but he gives information which may help you in reaching a decision if you are confronted with that necessity.

ACCIDENT PREVENTION IN HOSPITALS

Hospitals also have accidents, it appears. To head them off the National Safety Council and the Council on Planning and Plant Operation of the American Hospital Association through a safety committee have developed a cooperative program. For an annual fee of $5.00 to the National Safety Council, member hospitals of the Association will be provided monthly with supplies of posters, safety instruction cards, and other safety program materials, as well as a safety newsletter. Its author is Dorothy Pellenz of Crouse-Irving Hospital, Syracuse, N. Y., who gathers news and ideas from hospital administrators throughout the country.

The subscribing hospital in turn agrees to furnish statistics on accidents to the National Safety Council for analysis and measuring of program results and for possible reduction in employee compensation insurance rates.

GETTING UNIVERSAL CHEST X-RAYS

Since 1942 the New Jersey State Health Department has been carrying on free industrial and community x-ray surveys in which nearly 400,000 persons have been x-rayed. But it has a population of over 4½ million and more than a million gainfully employed industrial workers.

To spread information on how all may be x-rayed is the purpose of *X-Ray: the Picture of Health.* A well put together pamphlet tells the extent of tuberculosis, its incidence in the productive age group, and gives information as to how an industry or a community may have an x-ray survey. A six page list of industries that have already had surveys is included to encourage those who would not "be the first by whom the new are tried."

HAWAII'S FUTURE HEALTH PICTURE

In a well produced booklet of about 75 pages, the recommendations of Hawaii's 14 Postwar Planning Committees on Health are published by the

Public Health Committee of the Honolulu Chamber of Commerce. In 8 chapters covering various phases of public health activities extensive recommendations, totaling 173 in one chapter, for immediate action and for long-range objectives are given. Public Health Committee, Chamber of Commerce, Honolulu, Hawaii.

NPC PACKET PACKS A WALLOP

If you do not know the monthly publicity packet, with comments, of the National Publicity Council (130 East 22nd St., New York 10), the one of November 12 is a good one with which to start. About half a dozen items selected from Florida and Seattle and way stations between are excellent illustrations of getting your message across effectively —and simply.

MINNESOTA LEGISLATURE STUDIES COUNTY HEALTH UNIT PLAN

As an earnest of the interest among Minnesota citizens in developing a county health unit plan of public health service the Legislative Research Committee in November, 1948, published *County Unit Health Plan.* This is a joint committee of the legislature meeting quarterly and giving advance consideration to problems to be confronted in the next legislature.

Minnesota does not now have a county or district health unit law but one has been introduced in the current legislature. The Legislative Research Committee's report, which summarizes the health unit situation in the country generally, recognizes the need for better health service in the state. Its report poses two questions: Will the benefits match the cost? If so, where shall the expansion occur? The second question presupposes a choice between the expansion of state health districts into direct service units or the development of local health units.

The report is geared most directly to the financial situation. It points out the expensiveness of the Rochester-Olmstead County Health Department, which is really a loose federation of the public and private health agencies in the area, without noting that the entire county population is less than 40,000 and without suggesting the possibility of coöperative health services with other counties. It also apparently accepts as static the situation in St. Louis County where the organized county health department serves only one-fifth of the population of about 40,000 persons excluding the City of Duluth and all other organized townships and municipalities that have not requested inclusion in the county's program.

In this connection it needs to be pointed out once more that to say as this report does, that the 40,000 persons served by the St. Louis County unit is pretty close to minimum A.P.H.A. standards, is to misread the *Local Health Units for the Nation* report. The 50,000 minimum population is only one criterion; at least an equally important one is that one health unit should serve both the rural and urban areas of a county or counties for the very obvious reasons that trade and communication between rural and urban areas is constant, that expensive overlapping and confusion of services can be prevented, and that inequalities in urban and rural incomes can be balanced.

HEALTH UNLIMITED APPEARS

In October, *Health Unlimited* was born in the San Francisco Health Department as a quarterly publication to "help keep the public as well as professional persons informed on the best health practices, current research in the health field, and up to date knowledge about the city health resources, services, and facilities." The new baby was named by sanitarian Albert Martin competing with 169 entries by other staff members. The lead article of the first issue is Working Together in Public Health,

with joint authorship of the editorial board of 6 staff members. Looks as though coöperation were to be San Francisco's watchword.

A REPORT OF WORK, NOT NAMES

The report of the activities of the Indiana State Health Department for the two years 1946–1948 is notable for several things:

1. It has no long list of names and titles. One wouldn't even suspect that Leroy E. Burney, M.D., is the State Health Officer.

2. It is not afraid of the facts. Pictures and figures show Indiana in relation to other states—40th among 48 states in per capita state appropriations to health departments and less than 25 per cent of the population covered by full-time local health service.

3. The report is imaginatively illustrated and very readable.

POLIOMYELITIS TEACHING MATERIALS

Health workers report finding the *Poliomyelitis Science Unit,* which includes a text for high school students, a teachers' guide, and film slides, useful in educating the public.

Copies for quantity distribution are available without charge from the Education Service, National Foundation for Infantile Paralysis, 120 Broadway, New York 5, N. Y.

MISSISSIPPI LEADS IN RECRUITING DOCTORS FOR RURAL AREAS

The Mississippi Legislature of 1946 established a program of providing loans for young men and women in Mississippi to cover the expense of their medical education. The loans provide $1,250 per school year, or a maximum of $5,000 in four years. Applicants who are acceptable for enrollment in an approved medical school may undertake contracts to return after completion of a general rotating internship to a rural area approved by the State Medical Education Board, where the applicant must remain for a minimum period of two years. The loan, which bears 4 per cent interest, is discounted at 20 per cent of the total loan per year of medical practice in a rural area, so that if the young physician remains for five years the entire amount of his loan, plus interest, is credited to him. However, at the end of two years he may pay off 60 per cent of his loan, plus interest, and be free of contract obligations.

The Board supervising the loan program is made up of the Dean of the University School of Medicine at Oxford; the Executive Officer of the Mississippi State Board of Health; President of the Mississippi State Medical Association; a past president of the Federation of Women's Clubs in Mississippi; and a local superintendent of schools. Further details may be obtained from a brochure, *What the Medical Education Program Means to Mississippi,* Mississippi State Medical Education Board, Jackson.

CONNECTICUT'S FILM CATALOG

The film catalog of the Connecticut State Health Department is an attractive booklet called Health Educational Services. In addition to listing some 100 films, it also gives information about other health education services—slide-films, posters, exhibits, leaflets, and speakers. Bureau of Public Health Information, Connecticut State Department of Health, P. O., Station A, Box K, Hartford, Conn.

ALERTING THE POTENTIAL DIABETIC

In *Harper's Magazine* for January, C. Lester Walker, in "A Million Unknown Diabetics," brings to the general reading public the currently accepted information about diabetes and the possible preventive measures that should be universally known. For the known diabetic he says, "the diabetic today can live really strenuously" citing Mayor La Guardia

and tennis champion William F. Talbert in proof.

For the unknown diabetic he gives the warning of the American Diabetes Association:

Have a blood-sugar test made if: (a) You are 40 and overweight; (b) Any one of your ancestors ever had diabetes. —*Harper's Magazine*, 49 E. 33rd St., New York.

THE RED CROSS SUMMARIZES ITS VANPORT EXPERIENCE

The Red Cross, in summarizing its experience with the disastrous Vanport (Ore.) flood of last spring, found that all its neat disaster plans were not nearly enough. In "What We Learned When Vanport Vanished," E. A. Valentine, disaster Chairman of the Portland-Multnomah County Chapter, outlines the plans that were inadequate for the benefit of other disaster committees who may also have gaps in their planning. The one thing we find missing in this summary is any attention to the preventive aspects—namely, a concern with the bad building conditions that made the Vanport flood much more disastrous than it need have been even taking account of the Columbia River's worst rampage in 50 years. But perhaps it is unfair to expect a disaster organization to concern itself intimately with basic community conditions.

ANNUAL REPORTS

Boston's Health in 1947—This 76th annual report of the Boston City Health Department, with photographs of many of Boston's notable buildings, was prepared to coincide with A.P.H.A.'s 76th annual meeting in Boston in November, 1948. It is dedicated to the Association and reviews public health progress in the city during the 25 years since the Association last met in Boston. It is no surprise that heart disease and cancer in that order were the two leading causes of death both in 1923 and 1947. But it may be a sign of the times that accidents and diabetes were among the leading 10 in 1947 but not in 1923, and that alcoholism, among the leading 10 in 1923, had dropped out of this group by 1947.

TEXARKANA-BOWIE TAKE A BOW!

For the third successive year, Texarkana-Bowie County Health Unit has been the first one to submit its *Evaluation Schedule* in the Association's Annual Evaluation Project. W. L. Kitchens, M.D., is the Director of the Health Unit which covers a population of 72,400. The Chairman of the Health Committee is W. B. Harrell, M.D. Each year the *Schedule* has arrived in the Association office early in February. A good job is done in presenting the data and progress is shown in the use of the *Schedule*.

WORTH ACQUIRING

Aging: Family Health Series—Guide for Public Health Nurses No. 8—As with others in this series, this guide was prepared by the nurses of the Department of Educational Nursing of the Community Service Society of New York to suggest to public health nurses ways and means of working with older people. Community Service Society of New York, 105 East 22nd St., New York 10, N. Y., *15 cents* for orders under 100; *12 cents* plus postage for 100 or more.

Dihydrostreptomycin: A New Antibiotic in the Treatment of Tuberculosis—Squibb's professional service department has prepared a brief pamphlet primarily for physicians giving the facts about dihydrostreptomycin—why it was chosen, what clinical trials it has had, what forms of tuberculosis it affects, its dosage and administration, tolerance, and, finally, a number of precautions. This should be in a library of antibiotics with reference to tuberculosis. E. R. Squibb & Sons, 745 Fifth Avenue, New York.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

Voluntary Medical Care Insurance in the United States—*By Franz Goldmann. New York: Columbia University Press,* 1948. 228 pp. Price, $3.00.

The status of voluntary prepayment plans is, perhaps, the most important single issue in the turbulent arena of current medical care planning. In this study—designed as a companion volume to the author's *Public Medical Care*—one of the country's leading experts has undertaken the kind of careful analysis and appraisal that must underlie any national policy in the health services.

In this book, Dr. Goldmann has presented, first, an objective account of principles and prerequisites in the operation of voluntary medical care insurance plans. This constitutes one of the best summarizations now available of all related factors—actuarial, administrative, and medical. Particularly appropriate to current interest in the *quality* of organized service is the brief section on "Adequacy of Medical Care."

Succeeding chapters trace the origins and development of voluntary efforts in medical care, from the mutual benefit associations of the Civil War period to the present vast extension of Blue Cross and the complex organization of New York's Health Insurance Plan. The attitudes of those professional and lay organizations which have influenced the movement are fairly summarized. Each general type of voluntary plan—cash indemnity, hospital and physician's services, group practice, coöperatives—is then analyzed in terms of administration, service, and costs.

The book is completed by an overall estimation of the limitations and potentialities of voluntary plans. The author points out that the historical contributions of the voluntary approach have been inestimable, and that the combination of group prepayment and group practice must have a particularly significant place in any national program of medical care. He concludes, however, that the limited coverage, the restricted benefits, and the high costs of innumerable private plans preclude any serious expectation that the full needs of the nation can be met through such unaided efforts.

The presentation suffers from a profusion of statistical data in the text that might have been organized into tables or charts. One wishes, also, that the author had more forcefully applied his own experience with voluntary plan participation in European health insurance programs to the current issues facing the American people.

EDWARD S. ROGERS

Social Denmark—*A Survey of the Danish Social Legislation. Edited and published by Socialt Tidsskrift Copenhagen,* 1947. xv + 475 pp. No price given.

Denmark's efforts to increase the social security of its population have done much to make its name respected among the nations of the world. As in many other countries, Danish social legislation has grown out of old public assistance laws that had their roots in ecclesiastical and lay charities. The history of this legislation falls into three periods: the first, from the Reformation to about 1891, when a New Poor Law and an Old Age Pensions Act were passed; the second, from 1891 to 1933, during which most of the features that characterize the present situation were introduced; and

the third period, dating from 1933, when the existing social legislation was codified in one inclusive social security system, which has been modified only slightly since then.

The first sphere to be put on a government regulated and supported basis was sickness insurance, when the Rigsdag in 1892 passed a law concerning approved sick clubs. In some very important respects Danish sickness insurance is different from most other types. One of these is the fact that the administration is in the hands of autonomous, but governmentally regulated clubs. Another is the essentially voluntary character of membership. It should be remembered, however, that general prosperity in the Danish community has been greater than in most other European countries.

In addition to sickness insurance, the social security system includes old age and invalidity insurance, workmen's compensation, unemployment insurance, public assistance, child welfare legislation, maternity aid legislation, aid to widows and orphans, legislation organizing and regulating the labor market, and aid for housing and town planning. The volume under review gives an excellent picture of this comprehensive system. While the standard of living in Denmark was reduced during the war, it was possible to maintain the general system of social legislation. This survey of Danish experience is a definitely worth while contribution to an international exchange of social knowledge and experience. The volume is illustrated and has an extensive bibliography. GEORGE ROSEN

Public Health Engineering. Volume I—*By Earle B. Phelps and collaborating authors. New York: Wiley,* 1948. 644 pp. Price, $7.50.

This book is one of two volumes presenting a rather complete review of man's environment. The approach is made on the basis of the effect on man's health of the air he breathes and uses, the water he drinks and wastes, and the food he eats and wastes, and emphasizes some significant facts concerning control measures which can be instituted to create an environment favorable to man. The air and water "contacts" are discussed in Volume I. The food "contact" is to be published as Volume II. The field of public health engineering is presented as that field in which "engineering principles and techniques based on biological data are employed in the practice of public health." "It deals essentially with control of the environment with those modifications and protective and preventive measures that have been found desirable or necessary for promoting optimum conditions for health and well being."

The author states frankly in his preface that the book "is written primarily for the engineer who presumably has learned how to design and build, to teach him, in the light of present-day knowledge of sanitary science, what to design and build and why." It should be added that he should have had some experience and a certain orientation in the public health field generally to be able to use the book to greatest advantage. A student or a person new in the public health field might have some difficulty in accepting the simplified grouping of environment under three "contacts." Probably he would be surprised to find a discussion of bedbugs, lice, and fleas in a chapter on insect control under Part I—The Air Contact.

This volume deserves a place in the public health library of every health department along with other notable books on public health practice, such as those written by Rosenau, Dunham, and Emerson. It fills in many important items involving sanitation barely discussed in the books mentioned. It brings into one reference a compendium of principles of sanitary science and useful data, including some formulas

that could only be obtained heretofore by extensive search in many separate texts. Pertinent references needed to complete a more exhaustive study of engineering *per se* are listed after most of the chapters.

Collaborators in the preparation of this volume included Dr. Harry D. Pratt, Scientist, U.S.P.H.S., who wrote the chapter on Insects and Insect Control; Professor John M. Henderson, School of Public Health, Columbia University, who revised the section dealing with drainage; and Professor C. J. Velz, Manhattan College, who collaborated in the preparation of the whole of Part II—The Water Contact.

WILLIAM T. INGRAM

Principles of Healthful Living: For the Individual and the Community—*By Edgar F. Van Buskirk. Edited by Carl L. Kline. New York: The Dryden Press.* 474 pp. Price, $3.50.

In this revised edition of the work by the same title, published in 1938, the author has used the same functional approach and manner of presentation. The content has been brought up-to-date and an entire new section has been added devoted to family and community health.

In this volume, designed primarily for first and second year college students, the author discusses principles of healthful living from the viewpoint of the individual and that of the total community. The first part includes reference to basic concepts in the interest of giving the student an introductory perspective and understanding of the general nature and scope of the study as a whole. In part two. composed of eleven chapters, the individual aspects of healthful living are stressed, with particular reference to the practical everyday health needs of the individual student.

Part three contains eight chapters, with emphasis upon group health aspects of family and community living: mental health, mental handicaps, progress of medicine, family health, disease control in family and community, and public health agencies. In the appendix, the author has listed a good bibliography of one hundred books found useful for supplementary reading.

This revised volume is recommended for use with college students and should be of interest to educators and public health workers as a general reference.

A. HELEN MARTIKAINEN

Pathology—*Edited by W. A. D. Anderson. St. Louis: Mosby,* 1948. 1453 pp. 1183 illus. Price, $15.00.

Public health workers need a dependable source of reference in the broad field of pathology and are frequently interested not only in the more familiar aspects of pathology but in the aspects of exotic diseases. The reviewer has had an opportunity to test the information available in this magnificent volume in a dozen areas with exceptionally satisfactory results. Especially outstanding are the chapters on Rickettsial and Viral Diseases, on Fungus Infections, on Protozoal and Helminthic Infections, and on Vitamins and Deficiency Diseases. Another outstanding chapter is that on Physical Agents in the Causation of Injury and Disease, covering some of the medicolegal aspects important to physicians in public health. Throughout the volume the references include many recent sources, and the illustrations, including a number in color, are superb. The volume is highly recommended.

REGINALD M. ATWATER

The Leptospiroses—*By P. H. van Thiel. Leiden, Netherlands: Universitaire Pers Leiden,* 1948. 231 pp. Price, 16.50 florins.

This book contains the most carefully detailed and complete review and summary of the present-day knowledge

on the Leptospirae and the diseases caused by them since the monograph by Walch-Sorgdrager which appeared in 1939. In 22 chapters the author discusses the morphology, classification, diagnosis, pathogenesis, and clinical and therapeutic aspects of the leptospiroses. Particularly the presentation of the basic epidemiological features is well documented by judicious selection of the important facts. The presentation is thorough and critical. Those coming in contact with the leptospiroses realize the multitude of unsolved problems; however, a surprising number of solutions will be found in this treatise by van Thiel.

A remarkable number of concepts are touched upon and appraised. Therefore, the content of the text will be useful to the research worker. Excellent illustrations and summary tables are added to the text.

The manuscript was prepared during the war years. References to the very recent literature are not included, although the bibliography, which does not record articles already listed in older monographs, covers 21 pages. The defense mechanism of the host against Leptospira is not discussed.

K. F. MEYER

Advances in Pediatrics, Vol. 3—*Editorial Board: S. Z. Levine, Allan M. Butler, L. Emmett Holt, Jr., and A. Ashley Weech. New York: Interscience Publishers,* 1948. 363 pp. Price, $7.50.

This is the second post-war issue of *Advances in Pediatrics,* and like the two preceding volumes it presents a collection of authoritative and readable monographs of contemporary interest and importance to pediatricians and general practitioners.

The authors of each of the eight articles in the current number are recognized authorities in their respective fields, and each monograph is a complete, scholarly, up-to-date, and practical piece of work in which the author interprets information from background material and synthesizes it with his own knowledge and experience. Quoting from the preface, the eight topics "encompass a variety of subjects and the whole age span from birth through adolescence." Two of the reviews are related to emotional, psychologic, and social problems: "Emotions and Symptoms in Pediatric Practice," by Milton Senn of Cornell University, New York; and "Puberty and Adolescence: Psychologic Considerations," by Hilde Bruch of the College of Physicians and Surgeons, New York.

The remaining six articles cover recent advances in other fields of interest, e.g., "Effects of Birth Processes and Obstetric Procedures upon the Newborn Infant," by Clement A. Smith of Harvard Medical School; "Therapeutic Agents in the Treatment of Epileptiform Seizures," by William Lennox of Harvard Medical School; "Abnormalities and Variations of Sexual Development during Childhood and Adolescence," by Lawson Wilkins of Johns Hopkins; and the three shorter articles, "Viral Hepatitis," by Joseph Stokes, Jr., of the University of Pennsylvania; "Retrolental Fibroplasia," by T. L. Terry; and "The Osteochondroses," by Beckett Howorth, this latter with beautiful plate illustrations.

It would be difficult to find anywhere a more excellent and rewarding review of the recent important pediatric advances. ELINOR F. DOWNS

Proceedings of an Inservice Training Course in Health Education Techniques—*Territorial Department of Health, Honolulu, Hawaii,* 1948.

Health departments and other health agencies would do well to study this report. These proceedings record the step-by-step development of a six session course on health education tech-

niques. It contains detailed descriptions of each session, covering content, method, references, assignments, and evaluation.

Planned for the personnel of the Territorial Department of Health, it was predicated upon the fact that everyone in the department is concerned with health education and therefore should be familiar with presently accepted techniques. Practically every aspect of public health was represented in the group and covered every level of administration.

Health educators of the Department of Health, the Tuberculosis Association, and the University of Hawaii participated in the planning and were responsible for the conduct of the course. They are to be congratulated for a job well done. S. S. LIFSON

Let's Tell the Truth about Sex—*By Howard Whitman. New York: Pellegrini & Cudahy, Inc.*, 1948. 242 pp. Price, $2.50.

Mr. Whitman is a professional writer who has conferred extensively with outstanding authorities on marriage, parent-child relationships, and on the educational principles involved in transmitting both attitudes and factual information concerning sex to children. He has also read widely concerning these subjects. His book has great value as a professional writer's interpretation in popular language of current thought among leading proponents of what is usually referred to in a confusingly over-simplified manner as "sex education." This outstanding value of the book is lost unless it is read and considered as a whole.

The title is no indication of the value of the book. Apparently written primarily to help parents answer children's questions concerning sex, the book rightly emphasizes the greater importance of attitudes and feelings as compared to factual data. However, suitably phrased answers to the more common questions children may ask at various ages are given with the understanding that parents must adapt them to their own personalities and feelings. Certain statements in the book have to be recognized as essentially true, although not specifically true in many individual instances, such as, "A doctor, by examinations and tests, can easily determine whether a person has a venereal disease."

The tendency of a professional writer to use a vigorous and dramatic phraseology has on the whole been curbed in this book, but not completely. If such titles as "Save Sex—and Maybe Civilization, Too" convey an impression of flamboyancy leading to a conclusion that the contents are probably too superficial, a careful reading of the book as a whole will reveal it to be a generally sound interpretation of current authoritative thinking on the subject matter with which it deals. Although written chiefly for parents, professional persons not already familiar with modern concepts of education in this field may, through careful reading of the book, gain a valuable appreciation and an up-to-date understanding of the subject.

ADOLPH WEINZIRL

Nursing for the Poliomyelitis Patient—*Prepared and published by the Joint Orthopedic Nursing Advisory Service, N.O.P.H.N., 1790 Broadway, New York City.* 88 pp. Copies are free on request to physicians, nurses, physical therapists and other allied professional groups.

This handbook is a revised compilation of material from three sources, all of which are publications of the National Foundation for Infantile Paralysis: No. 22, Nursing Care of Patients with Infantile Paralysis, by Jessie L. Stevenson, 1940; No. 45, Guide for Nurses, Joint Orthopedic Nursing Ad-

visory Service, 1944; No. 49, Nursing Care of the Patient in a Respirator, by Carmelita Calderwood, 1944. The need for drawing together these three references has been felt for some time. The writer understands that some workers have decried the omission of the diagrams (from No. 44) showing how wool packs may be cut most economically from blanket material. The Joint Orthopedic Nursing Advisory Service will make up for this deficiency by forwarding on request mimeographed copies of the deleted diagrams.

As its title indicates, this handbook is devoted to discussions of specific nursing problems in the various stages of the disease. The importance of total care is emphasized throughout. The first nine pages include necessary background data on such topics as the Nature of the Disease, Method of Spread, Signs and Symptoms, Incubation Period, etc. Five drawings of bed positions, application of lay-on and pin-on packs, and crutch walking gaits, as well as a few photographs on care of the bulbar and respirator patient, add to the value of the handbook as a teaching aid.

The reviewer has heard much praise of this publication from instructors in orthopedic nursing, and from nurses who have responded to calls from epidemic areas. Some of the latter have read it en route by plane to the epidemic area. Others have said: "I was rarely without it while on duty. Where may I get copies for my friends who are always trying to borrow mine?"

MARY MACDONALD

Practice of Allergy—*By Warren T. Vaughan (2nd ed.). Revised by J. Harvey Black. St. Louis: Mosby,* 1948. xx + 1132 pp. Price, $15.00.

Allergy as a branch of medicine is an outgrowth of certain laboratory observations grouped together under the general rubric of experimental anaphylaxis. Clinical forms of allergy, however, occur much earlier in medical literature. Leonardo Botallo, in 1565, and Johann Binninger, in 1673, described conditions which we would now call allergic. Better known is John Bostock's description in 1819 of his own case of hay fever. It was not until the turn of the century, however, that a basis was laid which made possible the development of clinical allergy. The progress made in this field of medicine since then is reflected in this massive volume of 1132 pages.

Written for physicians and other serious students of allergy, this treatise can be of considerable value to public health workers. Health officers, industrial hygienists, and others who may be consulted in their communities on matters of allergy can turn to the volume under review for dependable, accurate information. This book is recommended as a reference for public health workers.

GEORGE ROSEN

Malaria Control on Impounded Waters—*By E. L. Bishop and M. D. Hollis, Editors. U. S. Public Health Service and Tennessee Valley Authority,* 1947. *Washington, D. C.: Supt. of Documents, U. S. Govt. Ptg. Office,* 1948. 422 pp. Price, $2.00.

Based largely on the extensive experience of the U. S. Public Health Service and the Tennessee Valley Authority with the control of malaria in connection with impounded waters in the southeastern United States, and with a single *Anopheles* vector, this book is a valuable contribution to our knowledge of a particular phase of malaria control. Its value, however, is not limited to this restricted phase of the subject, for much of the material is of general interest to all mosquito control specialists and malariologists.

The most valuable chapters, which are unique among present published material, are those dealing directly with reservoir problems. These are Chapters III,

"Reservoir Preparation," IV, "Permanent Marginal Measures," V, "Water Level Management," VI, "Shore Line Maintenance," and XVI, "Small Reservoirs." Another very valuable chapter is XIII, "The Relation of Plants to Mosquito Control."

There is a series of appendices, among which "C," containing specifications for chemicals used in mosquito control, and "D," containing lists and descriptions of equipment, tools, and supplies, are particularly useful.

Certain chapters, such as XI, "Malaria Mosquitoes," and XII, "Malariology," could have been eliminated on the ground that these subjects have been more adequately treated elsewhere.

The book is unusually well illustrated. There are many photographs, a number in color, and the numerous tables and diagrams are excellent.

HAROLD F. GRAY

The Psychological Origin and Treatment of Enuresis—*A Practical Discussion of Bed Wetting—By Stevenson Smith. Seattle, Wash.: University of Washington Press,* 1948. 70 pp. Price, $1.75.

This is a small, simply written, 68 page book, the first 46 pages of which are written especially for parents and the remaining pages contain a further and more technical discussion of the problem with references to studies previously made and with discussion of different opinions as to etiology and the relationship of enuresis to physical pathology, familial tendency, depth of sleep, disturbing emotions, personality, social adjustment and sexuality. There is a two page bibliography.

Dr. Smith points out that before any attempt is made to correct enuresis the parent-child relationship must be improved by conscious effort on the part of the parent to be a more attractive person to live with. When this has been accomplished the child is ready to plan and coöperate in an effort to prevent enuresis. He describes several methods that may be tried and explains that any method of obtaining bladder control that is not carried out properly may become an added stimulus to bed wetting. It is pointed out that permitting a young child to urinate while he is half asleep rather than wake him thoroughly is training for bed wetting.

Since this book is short, simple, and presents easily understood and logical concepts, it is recommended for the use of parents and public health personnel.

MARION HOTOPP

Zinsser's Textbook of Bacteriology—*By David T. Smith, Donald S. Martin, Norman F. Conant, Joseph W. Beard, Grant Taylor, Henry I. Kohn, and Mary A. Poston, all of Duke University School of Medicine (9th ed.). New York: Appleton-Century-Crofts,* 1948. 992 pp. Price, $10.00.

From the first edition in 1910 by Hiss and Zinsser through the eighth by Zinsser and Bayne-Jones, this classic *Textbook of Bacteriology* has been a favorite with students of bacteriology, public health, and clinical medicine. The authors of this ninth edition have endeavored "to keep inviolate the basic biological approach to bacteriology and, at the same time, to emphasize the public health significance and the practical importance of certain of the biological characteristics of the organisms."

In comparison with the eighth edition, the general arrangement remains the same. However, each chapter has been revised fully in line with recent investigations, and references are notably to recent literature. The discussion of the sulfonamides has been expanded and a section on antibiotics added. There is a new chapter on pleuro pneumonia-like organisms, and the sections on bacterial metabolism, immunology, fungus and viral diseases have been rewritten entirely. The many new illustrations in-

clude beautiful electron micrographs.

Bacteriologists particularly interested in the genus *Salmonella* will be glad to find the Kauffman-White Schema (1946) for antigenic structure. The student of medical mycology will be encouraged to hear that "the difficulties are largely psychological," and he will find an expanded and satisfying section on the subject. In fact, teachers, students, and workers who have awaited this revision with some impatience will not be disappointed. P. L. KENDRICK

Practical Manual of Diseases of the Chest — *By Maurice Davidson (3rd ed.). New York: Oxford University Press,* 1948. 670 pp. Price, $16.50.

The author, writing out of his clinical experience, has as his objective the production of a book which will help medical students and practising physicians in applying practically our clinical knowledge of chest diseases, omitting the circulatory system. He does not claim to be a pathologist.

About a fourth of the book is occupied with preliminary considerations and with diseases above the terminal bronchi, another fourth with pulmonary tuberculosis, and the other half with various non-tuberculous conditions in the lungs and pleura.

Readers in the United States will find this book interesting though differing somewhat from similar ones written in this country. For example, this author gives relatively more attention to bronchitis and bronchiectasis; drugs are prescribed more freely, some 50 sample prescriptions being listed at the end of the volume; the socio-economic factors in relation to tuberculosis mortality are stressed far less; a less radical approach to the surgical treatment of chronic empyema is advocated; less space is given to the discussion of penicillin in pneumonia than to quinine, alcohol, or morphine; streptomycin in the treatment of tuberculosis is not mentioned, although the use of calcium, insulin, tuberculin, gold and iodine is discussed at some length.

There is a good chapter on sarcoidosis. Histoplasmosis and coccidioidomycosis are not mentioned. A modern view is taken of the problem of bronchogenic carcinoma. The x-ray reproductions are excellent.

In the bibliography given at the end of each chapter there are very few references dated later than the last previous edition in 1941. Most of the references are to British sources.

In general this is a readable volume, well documented, written by a man of rich clinical experience. He is not dogmatic but tries to present a balanced judgment regarding alternative theories and therapeutic procedures.

JOHN H. KORNS

A Health Program for Colleges— *A Report of the Third National Conference on Health in Colleges, May 7–10, 1947, New York, N. Y. New York: National Tuberculosis Association,* 1948. 152 pp. Price, $2.00.

The National Tuberculosis Association is to be congratulated for the support which it has given to this Third National Conference on Health in Colleges and this report. This volume contains a statement of the objectives of the Conference, orienting addresses by Kendall Emerson, M.D., and Alexander G. Ruthven, Ph.D., President of the University of Michigan, followed by chapters on college administration and the health program, the health service, health education, physical education and sports, healthful living, and finally, special health problems.

Without doubt, this is the definitive reference with regard to the subject and is to be commended for its breadth of vision and its recognition of the fact that we must not be content with present achievements in this field.

REGINALD M. ATWATER

Clinical Laboratory Methods and Diagnosis—*By R. B. H. Gradwohl. (4th ed.) St. Louis: Mosby,* 1948. 3 vols. 3,275 pp., 1,111 illus., 58 color plates. Price, $40.00.

The 4th edition of this comprehensive manual closely follows the pattern of previous editions but has again been enlarged and expanded. The work grew from a single volume to two volumes with the 3rd edition in 1943 and has now become a three volume text. As the author states in the preface, it has also outgrown the capacity of a single author and many experts in special fields are listed as collaborators.

The scope of these volumes can perhaps best be indicated by naming the division headings. The first two volumes deal with urine analysis, blood chemistry, hematology, blood groups and transfusion, gastric analysis, puncture fluids, feces, bacteriology, serology, postmortem examinations, tissue cutting and staining, preparation of museum specimens, toxicology, crime detection, basil metabolism, and electrocardiography. These two volumes carry a single index and can be considered as one work. The third volume is actually a separate text on parasitology and tropical medicine written jointly by Dr. Gradwohl and Dr. Pedro Kourí of Havana, Cuba. It contains sections on protozoölogy, helminthology, and diseases caused by spirochetes, viruses, and arthropods.

Each of the chapters contains detailed descriptions of laboratory technics closely interwoven with a discussion of the significance of the findings, with frequent correlations with clinical evidence and case histories drawn from many sources. Several of the sections are actually textbooks in themselves, for instance, the section on hematology occupies 399 pages and is followed by a chapter of 166 pages on blood groups, including Rh and transfusion.

It is impossible in a review to convey adequately an idea of the wealth of detail that appears throughout the work, but as an example the section dealing with Salmonella presents: the clinical manifestations of salmonellosis, the nomenclature, morphology, and biochemistry of the group, the antigenic structure, including H-O, Form, V-W, S-R and phase variations, typing procedures and a complete tabulation of the antigenic structure of some 150 species. One finds a similar complete detailed coverage of practically all the subjects.

The volumes are profusely illustrated with photographs, photomicrographs, color plates, sketches, diagrams, and charts. Source references are given throughout the text as footnotes.

While the book deals primarily with clinical and diagnostic medicine, it also includes a short section on sanitary bacteriology, including restaurant sanitation, the microbiology of frozen foods, and the bacteriological examination of water and milk. Unfortunately this section does not seem to have been brought up-to-date in the same manner as other sections. Methods for the bacteriological examination of water and milk do not conform to present A.P.H.A. practice. Neither brilliant green bile lactose broth nor T.G.E.M. agar is mentioned, and all incubation temperatures are specified as 37°. The reference for the methylene blue reduction test is the 6th edition (1934) of A.P.H.A. Standard Methods which is at considerable variance with the current edition.

As public health laboratories are called upon to increase their scope of service in respect to clinical and diagnostic procedures relating to all diseases, they will need authoritative reference works covering the entire range of clinical practice. The present volumes are eminently suited to meet such needs.

E. K. KLINE

Survey of Food and Nutrition Research in the United States, 1947—*By The Committee on Survey of Food*

and Nutrition Research of the Food and Nutrition Board, C. G. King, Chairman. Washington: National Research Council, 1948. 306 pp. Price, $1.00.

As the title implies, this book is a compilation of nutrition research projects under way in 1947 in academic, governmental, and industrial laboratories. The work gives the titles of 4,086 projects, classified under physiology, chemistry, technology, economics, bacteriology, and psychology, with numerous sub-classifications. The listing of individual projects also gives the institution and any supporting organization in each case. A list of 4,523 investigators with their institutional connections is also given. A complete subject index is included.

The book should prove to be a valuable reference work in the field covered.

PAUL L. DAY

A Program for the Nursing Profession—*By the Committee on the Function of Nursing. New York: Macmillan,* 1948. 106 pp. Price, $2.00.

A Program for the Nursing Profession prepared by the Committee on the Function of Nursing is a momentous document in more ways than one. It springs from a committee of 12 members, nine of them representing eastern universities, which undertook an appraisal of the nursing situation at the invitation of the Division of Nursing Education of Teachers College, Columbia University. Five doctors and three nurses served on the committee. It is a brief report, undocumented but supplied with some general references to source material.

The report presents in terse form the current nursing situation in its social and economic aspects now familiar to professional groups, but goes far beyond the present. It sets a goal for 1960 of a ratio of two practical nurses, trained by a year of preparation in an approved school of practical nursing, to one professional nurse, prepared in a 4 year program in a college or university with school of nursing affiliation. It assumes the gradual complete disappearance of the present 3 year course from which four-fifths of professional nurses are now drawn. Under this plan a total of 600,000 nurses would be anticipated in 11 years.

Coming as it does from a thoughtful group of experts and as a partial corollary of the Brown report (*Nursing for the Future*), these recommendations deserve very careful study and discussion and quick action if they are to be implemented in time to realize the goal. The most serious lack in the report seems to this reviewer, scant attention to the possibility of (a) failure to recruit the 56,000 practical nurses needed each year to supply the quota in 1960, and (b) the difficulty of covering the necessary training in 12 months in what will be converted professional schools. At present the 58 approved schools of practical nursing offering 9–18 months courses graduate about 1,100 nurses yearly and are not filled to capacity, while the subject matter covered is on a more elementary level in most instances than that suggested for the new practical nurses.

If ever a report presented—that well worn word—"a challenge," this is it.

DOROTHY DEMING

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

There Are about 148,000,000 of Us —Our population increased 2½ millions last year thanks to a near-record of births and the lowest death rate ever plus a little immigration. Unless something unforeseen happens we should exceed the 150 million mark in the 1950 census.

ANON. Population Increase Large in 1948. Statist. Bull. Metrop. Life Insur. Co. 29, 12:1 (Dec.), 1948.

Required Reading — Pseudo-scientific and plain nostrums cunningly foisted on credulous doctors and desperate try-anything cancer victims are told off one by one. Then come the treatments based upon theories of ques-

tionable promise. In somebody's eyes you may appear as an expert. So be prepared.

ANON. Cancer and the Need for Facts. J.A.M.A. 139, 2:93 (Jan. 8), 1949.

Tracer Atom's Anniversary—Professional curiosity will drive you to this symposium on atomic energy and its relations to medical research and human welfare generally. In it we're promised a lot more information about these subjects through scientific papers and books now in the throes of composition.

AEBERSOLD, P. C. Isotopes for Medicine (and two related papers). J.A.M.A. 138, 17:1222 (Dec. 25), 1948.

Mental Vitamins—This is a plea—and a delightfully presented plea—that clinicians and nurses in children's clinics give attention to relieving emotional difficulties as well as bodily ailments. Modern drugs and modern parent-training give more time to think about minds, says the writer. The urge to quote most of the paper is strong.

ANDERSON, C. W. Some Aspects of the Mental Welfare of Children and Infants. Pub. Health 62, 3:47 (Dec.), 1948.

Note for Your Notebook—Epidemiologic studies suggest three ways by which Q fever may have been spread in a recent outbreak: working in a dairy, living close to a dairy or stockyards, drinking raw milk.

BECK, M. D., *et al.* Q Fever Studies in Southern California. Pub. Health Rep. 64, 2:41 (Jan. 14), 1949.

New-borns Will Respond to Antigens—At the first, fifth, and ninth week of life 200 babies were given a triple antigen of diphtheria and tetanus toxoid and pertussis vaccine. A month later all infants showed a "protective level" titre against tetanus, 84 per cent were found safe against diphtheria, and 60 per cent were considered to be protected against whooping cough. A booster dose later raised the percentage of immunes in the latter categories.

DI SANT' AGNESE, P. A. Combined Immunization Against Diphtheria, Tetanus and Pertussis in Newborn Infants. Pediatrics 3, 1:20 (Jan.), 1949.

Social Security—Public medical care, and health and welfare services already established, plus extensions and supplements reasonably to be expected, plus growing coverage of voluntary prepayment schemes are all added up into a comprehensive picture to preface a measured statement of the A.M.A.'s reasons for opposing compulsory sickness insurance.

FISHBEIN, M. Health and Social Security. J.A.M.A. 138, 17:1254 (Dec. 25), 1948.

Good, Solid Words Are These—If a person eats more than he needs he grows fat; if less, he gets thin. The causes are conjectural, but one can be certain that emotions, training, and habit are influential. Endocrine disorders rarely are responsible. Can you resist reading the rest?

GASTINEAU, C. E., *et al.* Treatment of the Fat and the Lean. J.A.M.A. 139, 2:86 (Jan. 8), 1949.

After Careful Examination—In the wake of the 1947 New York City smallpox epidemic, 5 million were vaccinated in a hurry. Following wholesale immunization, there occurred 45 cases of encephalitis that may have been post-vaccinal. Most made a complete and prompt recovery. The 4 who died showed, post-mortem, no characteristic signs.

GREENBERG, M., AND APPELBAUM, E. Post-vaccinal Encephalitis. Am. J. M. Sc. 216, 5:565 (Dec.), 1948.

Their Goal Remains the Same—As everyone but the office janitor must know by now, revised "dietary allowances" appeared in 1948. This excellent discussion of the changes—which

are essentially of a minor nature—will prove useful for you as a reminder of what the allowances are, and are not, supposed to be.

JEANS, P. C. Recent Revisions in the Recommended Dietary Allowances. J. Am. Dietet. A. 25, 1:13 (Jan.), 1949.

We Could Tell Him a Few Things—England has abandoned compulsory smallpox vaccination—which hasn't been very compulsory for many years. In the course of time the population will be largely unprotected. What will happen? In view of the long experience of one unvaccinated town there is no real cause for alarm, says this M.O.H.

MILLARD, C. K. The End of Compulsory Vaccination. Brit. M. J. 4589:1073 (Dec. 18), 1948.

Young Old People—Inspired words are these! "Life ends for many old people as naturally as it began, with little distress, in the midst of full, forward-looking participation in society, with no period of custodial care or sitting on the side-line benches. The geriatrician believes that this happy ending can be achieved by many more."

MONROE, R. T. Medical Problems of Old Age. New England J. Med. 240, 2:57 (Jan 13), 1949.

"New Profession . . . Health Physicist"—If your digestive capacity is equal to the job, you'll get a lot of nourishment from the capsule doses of scientific findings in a great variety of subjects ranging from genes to cosmic rays and not neglecting nuclear energy's effect on public health.

MOULTON, F. R. The A.A.A.S. and Organized American Science (and) Abstracts of Papers Presented at the A.A.A.S. Centennial Celebration. Science 108, 2813:573 (Nov. 26), 1948.

Productive Field—Prevalence rates of 8 per cent + of unsuspected pulmonary tuberculosis among the inmates and 2.7 per cent among the attendants in 7 state mental hospitals are statistics worth remembering.

ORCHSLI, W. R. Tuberculosis Control Program of Nine California Mental Institutions. Pub. Health Rep. 64, 1:4 (Jan. 7), 1949.

Intellectual Adventure—Can you write genially and intelligibly about your own particular job in words so clear that an educated layman will respond, "Well, I'm glad to get that straight, at last."? For an outstanding example of what you ought to be able to do, hunt out this dedicatory address.

RABI, I. I. The Atomic Nucleus, A New World to Conquer. Science 108, 2816:673 (Dec. 17), 1948.

Dental Health Goals—Mostly this paper is about the dental research projects and dental health field demonstrations now underway by the U. S. Public Health Service. There is a lot more in it which should be known by any health worker.

SCHEELE, L. A. A Forward Look at Dentistry. J. Am. Dent. A. 37, 6:627 (Dec.), 1948.

Widely Variable, They Pronounce It—In case you'd like to know what the mumps virus looks like, there are some excellent electron micrographs accompanying this article. What else you will get from it, I cannot predict, for the discussion was way over my head.

WEIL, M. L., *et al.* Purification pH Stability and Culture of Mumps Virus. J. Immunol. 60, 4:561 (Dec.), 1948.

Public Health in Foreign Periodicals

GEORGE ROSEN, M.D., PH.D.

POPULATION, like race, is one of the most publicized biological factors implicated in social developments. Historians, for instance, have endeavored to explain the decline of Rome as primarily a demographic phenomenon. Other social scientists have been interested in population because of particular contemporary problems. In the 19th century this was a fear of overpopulation and population pressure. Later, in Western Europe, the decline of fertility led governments to introduce various measures designed to affect the trend of fertility. Specific problems thus led to the development of population policies.

Among the factors affecting population, war takes a prominent place. The effects of World War II will be felt for many years, just as the impact of the war of 1914–1918 is still clearly seen in the demographic structure of Germany.[1]

CIVIL WAR AND DEMOGRAPHY IN SPAIN

The Spanish Civil War has been called a rehearsal for World War II. It may therefore be of interest to consider the effects of the internecine struggle on the Spanish people before glancing at the influence of World War II on other European populations. To ascertain the impact of the Civil War on the population, Verdugo [2] studied the trend of certain demographic phenomena. Among these were birth and death rates, mortality of infants under 1 year, and of children aged 1 to 5, stillbirths, and the occurrence of such diseases as tuberculosis, typhus fever, typhoid fever, and smallpox. The period considered comprised the ten years from 1933 to 1942.

The birth rate declined considerably during the war but rose again in the post-war years. Nevertheless, it did not reach the level that had existed in 1936. General mortality, as well as infant and child mortality, increased from 1937 until 1940 when a decline set in. The stillbirth trend was variable, in general tending to diminish except for the years 1939 and 1942. Typhoid fever and tuberculosis increased markedly during the war years, the former especially in 1938 and 1939. However, following the termination of hostilities typhoid dropped rapidly, while tuberculosis has shown no appreciable tendency to diminish. Smallpox rose in some degree during the immediate post-war years, while typhus fever did not show an appreciable increase until 1941–1942. On the whole, Verdugo concludes, Spain has recovered quickly from the demographic disturbances occasioned by the Civil War.

EXAMINATION OF UNIVERSITY STUDENTS IN WÜRZBURG

The impact of the war and the immediate post-war period on a specific group of the German population is illuminated by an investigation reported by Bunse.[3] In the winter semester of 1946–1947, 1,750 out of the 2,500 students enrolled at the University of Würzburg were subjected to thorough clinical and röentgenological investigation. This represented 70 per cent of the student body. Among the male students, 80.2 per cent were in the 18–25 age group, while 91 per cent of the female students were in the same group. The group examined contained 1,422 male and 328 female students.

It was found that 10.2 per cent of the male students were underweight by 5 kilograms or more while among the fe-

male students only 2.4 per cent were underweight to this extent. Active tuberculosis was found in 0.77 per cent of the men. This may be compared with the figure of 1.35 per cent found among students in Munich and 0.42 per cent among students in Jena. Bunse also compares his finding with the result of examinations of Würzburg students in 1933–1935. At that time 0.3 per cent of the students examined were found to have active tuberculosis. On the basis of this comparison Bunse concludes that there has been almost a threefold increase in cases of active tuberculosis among Würzburg students.

Anemic states were not infrequent. Among male students 11.2 per cent were found to have hemoglobin values under 65, while 30.8 per cent had values under 70. In 17.5 per cent of the male students the number of erythrocytes was less than 3.5 million. Among the women students 34 per cent had hemoglobin values under 65, and 59 per cent under 70, while in 48.4 per cent the number of erythrocytes was under 3.5 million.

Refractive errors were found in 40.9 per cent of all the students. Among the male students 38.3 per cent were hyperopic and 2.4 per cent myopic. Among the women 38.7 per cent were hyperopic and 2.1 per cent myopic.

Cardiac findings, chiefly compensated mitral defects, are reported in 1.4 percent of the students. Most of these had been diagnosed previously.

BIRTHS IN DENMARK FROM 1940 TO 1945

Prior to World War II the Danish birth rate had been declining, but during the German occupation this trend was reversed and gave way to a rapid rise. Hedemann tries to explain this phenomenon.[4] In 1939 the absolute number of live births was 67,900 and in 1941 it was approximately 71,300. In 1944, however, the number had risen to 90,600 and in 1945 to 95,100. During the occupation period about a third of a million babies were born. Of these it is estimated that only about 4,000 to 5,000 were attributable to German soldiers. There thus remains the problem of explaining a rise in the birth rate at a time when one might more reasonably expect it to fall. Hedemann is aware that demographic phenomena are not just biological, but that demographic change results equally from other elements deeply rooted in the social and psychological environment. Thus, he points out that in 1945 there were 20,000 more women between the ages of 15 and 49 than there had been in 1940. At the same time he also calls attention to an apparent change in social attitude toward childbearing, which became more "fashionable" than it was before the war. Such factors as constant employment, high wages, and restrictions on extramural social activities by curfews are also significantly implicated. It is clear that the increased birth rate resulted from the interaction of a number of factors, some measurable and others intangible.

CHINESE POPULATION PROBLEMS

Students of Chinese affairs have long been aware that population is a crucial factor in the health and welfare problems of China. The magnitude of these problems, in their quantitative as well as qualitative aspects, have led some to what is essentially a counsel of despair. Thus, in his recent book, *China. The Land and the People,* Winfield,[5] after discussing the state of public health, ends with the suggestion "that public health measures which can save millions of lives should not be practiced in China on a nationwide scale until the stage is set for a concurrent reduction of the birth rate. Existing misery and poverty can be permanently eliminated only when there are fewer, healthier people, with longer life expectancy and greater economic security. The future welfare of the Chinese people is more dependent

on the prevention of births than on the prevention of deaths." This is indeed Malthusianism with a vengeance! However, there is some evidence that the birth rate among the poor is somewhat lower than among the well-to-do. Abortion though illegal is practised, and it has been found that poor families do use contraception.[6] Furthermore the published literature shows that medical and public health workers in China in dealing with specific problems do not do so in terms of such a monistic either/or philosophy.
